3703	,, 26th	1165 - 1204	333 - 340

INDEX TO VOLUME II FOR 1931

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, *X* Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Pyelography and Urography; Lunacy and Mental Diseases; Sunlight and Ultra-violet; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

Abattoir, the public, and disease (Hal Williams), 1107
Abdomen, acute diabetic (R. D. Lawrence, C. G. Millman, and F. E. Pilkington), 530 (O)—Correspondence on, 583, 630
Abdomen, exploration of, indications for (Zachary Cope), 1333
Abdominal disease, acute, some neglected symptoms in (V. Zachary Cope), 94 (O)
Abdominal manifestations in rheumatism. *See* Rheumatism
Abdominal pain, review of book on, 570. *See also* Pain
Abdomino-pelvic diagnosis, review of book on, 949
Aberdeen. *See* Scotland
Abnormal Importations (Customs Duties) Act, 957, 1015
Abortion, charge of attempting to procure (Flora Wotherspoon), 1066
Abortion, criminal (Sir Bernard Spilsbury), 946
ABRAHAMSON, Leonard: Subacute bacterial endocarditis following removal of septic foci, 8 (O)
Abscess of breast, 85, 173
Absentee-ism due to catarrhal conditions (T. E. A. Stowell), 935 (O)
Académie de Médecine: Bi-centenary of the French Academy of Surgery, 552—Founds prizes for the best work on the cure of diabetes and of tuberculosis, 755
Académie Royale de Chirurgie, second centenary of, 1118—French surgery in the eighteenth century, 1118

ACADEMY, ROYAL, OF MEDICINE IN IRELAND: Election of officers, 704
Significance of the sulci of the brain, 117
Section of Medicine—Treatment of empyema, 1182
Section of Pathology—The sedimentation test, 1092—Carcinoma of appendix, 1093—Sarcoma of testis, 1093
Section of Surgery—cardiospasm, 948—Parotid tumour, 948—Some old journeyman surgeons, 948

Academy of Surgery, French, second centenary of, 552
Accident, an historical (death of Mr. Hushisson), 115
Accidents, motor, how hospitals can obtain payment from insurance companies for, 366
Accidents: Street, in London (parliamentary note), 227—Road, in the Metropolis (parliamentary note), 327—Road, doctors and, 359
Accion Medica: October and November issue devoted to tuberculosis, 1017
[illegible] the
[illegible], gastric, 1141
Acidity and malignancy, 1062
Acidosis and ketosis in children, 1064, 1157
ACLAND, the late Theodore Dyke, Order of the Nile conferred on, 407
Acne vulgaris, effect of sunlight on, 368
ACQUAVIVA, A.: *Les Dermatoses Insolitiques; leur Traitement par les Agents Physiques*, rev., 247
Acta Medica Scandinavica:—*Pathophysiology, of Hunger Pains; Gastrographic and Tutrimetric Investigations* (Oline Christensen), 393
[illegible]
[illegible], supplementum I: *Experimental Rickets* (F. Skaar), 576—Supplementum II: *Studies on the Mineral Metabolism during Pregnancy and Lactation and its Bearing on the Disposition to Rickets and Dental Caries* (Kirsten Utheim Tovernd and Gottorm Tovern), 575—Supplementum III: *The Distribution and Frequency of Rickets in some of the Fishery Districts of Finmark and Relation of Diet to the Disorder* (Johan Kloster), 575—Supplementum IV: *Blood Sugar in Normal and Sick Children* (Elisabeth Svensgaard), 1141
Acta Radiologica: *Malignant Tumours of the Tonsil* (Flis G. F. Perven), 653—*The Origin of Lymphosarcomatosis and its Relation to Other Forms of Leucosis in White Mice* (Carl Krebs, H. C. Bast, Nielsen, and Aage Wagner), 805
Actinotherapy, centres for (parliamentary note), 250

EPITOME

OF

Current Medical Literature.

JULY TO DECEMBER, 1931.

London:

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION, TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME II. 1931

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac, Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar, Eye Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A

Abdomina' conditions, simulated by cardiac symp oms, 511
Abdominal emergencies, spinal anaesthesia in, 555
Abdominal pain And skin diseases, 335—And the spastic colon, 571
Abdominal tumours *See* Tumours
ABEL K. Choline in treatment of menopausal symptoms 301
Abortifacient apiol poisoning, 600
ABRAMI P Immuno-transfusion in streptococcal septicaemia 479
Abrodil for intravenous urography, 266 *See also* Urography
Abscess brain, diagnosis of, 223
Abscess fixation the value of, 503
Abscess, perinephritic, 540
Abscess of the pregnant uterus 305
Abscess subphrenic 105
Acetabulum fracture of the, 544
Acetylcholine bromide [illegible] *urnal*,
[illegible] Non parasitic cysts of the liver, 4
Addison's disease Cortical suprarenal extracts in 243—Treatment [illegible]
Ad[illegible]
Ad[illegible]
Adrenaline action of, on abnormal uterine contractions, 215
Adrenaline intracardiac in neo natal asphyxia, 153
[illegible] lrogen ion
[illegible]
AGDEN G *Cyclic* changes in the glycogen content of the liver, 276
Alcohol as a cause of urethral discharge 249
Alcoholic emergency treatment of the 345
Alepol in leprosy 211
ALFANDI ESCO G The suprarenals in experimental rheumatism 223
Alimentary canal, defects of conduction in the 94
Alkali in salicylate therapy, value of, 518
Alkaline incrusted cystitis, 297
Allergic reactions the *nerve factor* in 349
ALLISTRATEN A Differential diagnosis of ovarian haemorrhage 304
AMANO K W Specific prophylaxis of meningitis 433
AMANTEA F Liver therapy in anaemia 210
Amaurosis during pregnancy, 326
Amenorrhoea and corpus luteum cysts, 16
Amicrobic pyuria 111
Amoebic dysentery carriers 439
Amoebic infestation treatment of, 294
Anaemia and [illegible]
Ana[illegible]
Ana[illegible]
Anaem[illegible] 591
[illegible] of
An[illegible]
A[illegible]
A[illegible]
A[illegible]
[illegible] avertin In neurological surgery, 51—In general surgery and obstetrics, 397
Anaesthesia induction in diabetics, 90
Anaesthesia, local, in fracture reduction, 395
Anaesthesia, percaine, 552, 553, 554
Anaesthesia, simple and combined, apparatus for, 83
Anaesthesia, sodium amytal, limitations of, 396
Anaesthesia, spinal, 89—Nupercaine in, 324—Extra ocular muscle paralysis following, 325—Intermittent traction in operations under, 341—In abdominal emergencies, 555
Anaesthetics, effect of on the blood lactic acid 323
Analgesia in labour, sodium amytal as an, 184
Anatoxine prophylaxis of diphtheria, 280
ANDERSEN, O The influence of fatigue on anti body formation and infection 601
ANDERSON, C C: Radium treatment of menorrhagia 484
ANDERSON, J S Two forms of the diphtheria bacillus 467
ANDERSON, N P Fumigation in superficial fungus infections, 420
ANDRE THOMAS Herpes zoster and encephalitis, 197
Aneurysm of the pulmonary artery, 176
Aneurysm, traumatic, of the temporal artery, 515
Aneurysms, intracranial, 3
Anima, agranulocytic, 410—X ray treatment of, 265
Angina pectoris treated by stovaine injections, 39—Etiology of, 130—Inhalation therapy in, 139
Angioma of the bladder, 29
Angioma of the brain, arterial, 116
[illegible] e-
Anthelmintic, tetrachlorethylene as an, 160
Antibody formation and infection, influence of fatigue on 601
Anti coagulant action of uroselectan 307
Antigen, Besredka's, complement fixation with, 149
Antiseptics, effect of dilution on, 125
Anti tetanic serum, mode of action of, 465
Antityphoid vaccination followed by herpes facialis 103
Anuria post-operative, hypertonic salt solution in, 573
Aortic stenosis, 385
Apiol poisoning, abortifacient, 600
Appendicitis in children, 231
Appendicitis, diagnosis and treatment of, 570
Appendicitis on the left side 61
APPERLY, F L The spastic colon and abdominal pain, 571
Aqueous fluid, circulation of the, 521
ARLOING F A filterable tuberculous virus, 189
Arsenic in chronic myelogenous leukaemia, 375
Arsphenamine-resistant syphilis, 232
Arterial embolectomy, 59
Arterial hypertension and uterine fibromata 559
Arterial spasm, traumatic 79
Artery, pulmonary, aneurysm of the, 176
Artery, temporal, traumatic aneurysm of the, 515
Arthritis chronic vaccine therapy in 519
Arthritis, suppurative, in the infant hip joint, 238
Artificial pneumothorax *See* Pneumothorax
Ascaris lumbricoides meningitis due to 314
Aschheim Zondek reaction *See* Zondek
ASHBY, W Poss Arterial angioma of the brain, 116
Asphyxia, neo-natal, intracardiac adrenaline in, 153
Aspiration of joint effusions, 474
Asthma, bronchial, ephedrine in, 592
Asthma, influence of resident hospital treatment on, 566
Asystole due to right ventricular stenosis, 337
Atophan compounds, toxicity of, 497
Atophan poisoning, treatment of, 450
Atropine in encephalitis lethargica, 321
AUBRY M Pulmonary and laryngeal tuberculosis, 405
Aurantiasis cutis Carotinaemia
AUPOUSSEAU, L Pneumococcal peritonitis 590
Auscultation, bistethoscopic binaural, 420
Australia post-vaccinal encephalomyelitis in, 229
Avertin anaesthesia *See* Anaesthesia
Axillary pleurisy *See* Pleurisy
AYMAN, D Essential hypertension, 93—Potassium thiocyanate in essential hypertension, 159
AYRES S Fumigation in superficial fungus infections, 420

B

BAAGOE K H Treatment of hay fever with pollen vaccines, 50
BABONNEIX, L Paraplegia following measles, 563
[illegible] ce of, 19
[illegible] rditis 510
[illegible] of, 467
[illegible] acteriolysis of, 221
Bacillus tubercle cultivation of from the blood, 65 563
Bacillus, tubercle, detection of in stained films, 382
Bacteriaemia influenzal, 150
Bacterial endocarditis *See* Endocarditis
Bacteriolysis of Koch's bacillus in the tissues, 221
BAIZE P The incubation period of measles, 585
BAKER, B M Syphilitic cardiac disease, 196
BALOG, A Recurrent necrosis of the pancreas, 110
BANI, U Phrenicectomy 391
BANSI H. W Circulatory efficiency in heart disease, 192
BANZET, P Surgical treatment of chronic obstructive jaundice, 33
BAPACH A L Oxygen administration in cardiac failure 418
BARBERO A Mycosis and pulmonary tuberculosis 332
BARCROFT J Effect of carbon dioxide on respiration 220
BARELLI L The reticulo-histiocytic apparatus and fat metabolism 360
BARETZ L H Phosphaturia, 536
BAREER, N W Protein therapy of thromboangiitis obliterans, 593
BARRAL P Insulin in ulcus cruris, 235
BARRE J A. Differential diagnosis of cerebral softening and tumour, 475
BASTIBLE, C The ketogenic treatment of epilepsy, 454

BATLEY, J. C. S.: Serum reaction following desensitization, 195
BAURE, E. E.: Diagnosis of abdominal tumours, 230

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

Including an Epitome of Current Medical Literature

WITH SUPPLEMENT

No 3678 SATURDAY, JULY 4, 1931 Price 1/3

The "Allenburys"

"CHARKAOLIN" GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins It combines the absorbent properties of highly activated vegetable charcoal with the well known toxin adsorbing qualities of "Osmo" Kaolin

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take

Descriptive literature and a clinical trial sample will be sent on application

ALLEN & HANBURYS LTD.

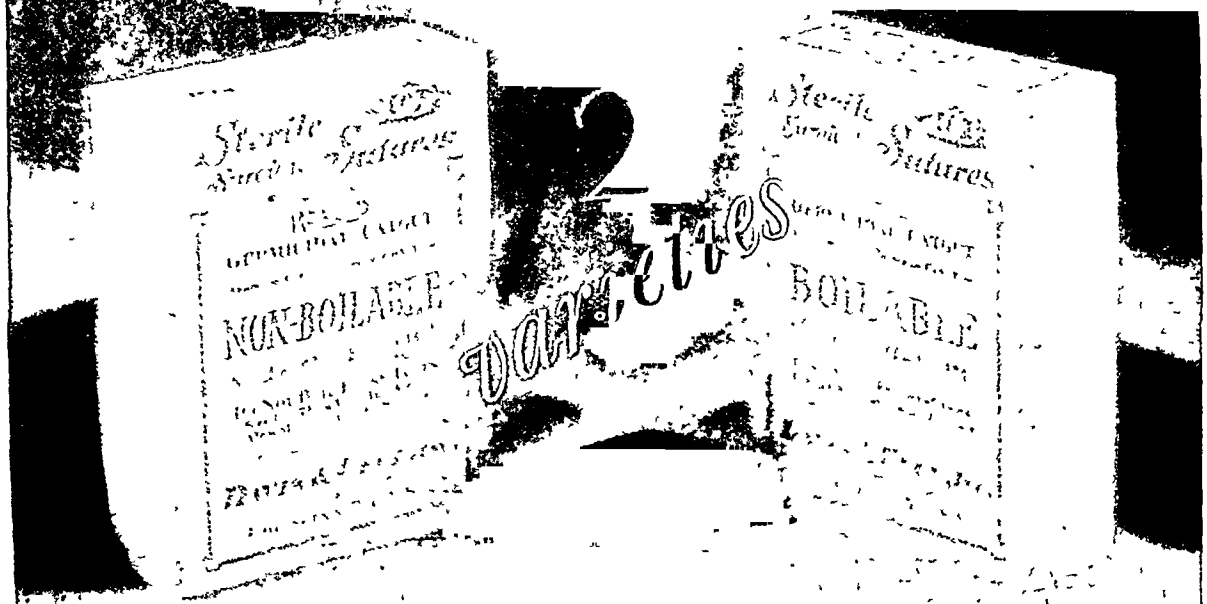
LONDON, E.2.

Aesculapius

SUPRARENAL CORTEX EXTRACT

(E.B.I. BRAND)

(in the treatment of Addison's Disease)



Prepared according to a method which is claimed to give maximum potency. It is issued in the form of a sterile, non-toxic solution, 1 c.c. being equivalent to 30 grammes of Cortex. It is completely free from Adrenalin, Albumen, poisonous metals or other disturbing substances, and it is adjusted to a pH which renders it eminently suitable for intravenous or subcutaneous injection. 5 c.c., and in certain cases possibly more, administered twice daily, for three days, or longer, is claimed to give satisfactory results.

Supplies are available, and orders will receive prompt attention.

Prepared at—
Evans' Biological Institute, Higher Runcorn, Cheshire.

EVANS SONS LESCHER & WEBB, LTD.
LIVERPOOL. LONDON.

D & G Kalmerid Catgut

The NON-BOILABLE variety is prepared for those desiring a heat sterilized suture possessing the maximum of flexibility.

The BOILABLE variety is prepared for those accustomed to sterilize the exterior of the tubes by boiling or autoclaving.

C. F. THACKRAY - PARK ST., LEEDS - 252 REGENT ST., LONDON, W.1

D & G SUTURES ARE ISSUED FOR USAGE UNDER MINISTRY OF HEALTH LICENCE 032-C

AN INDEX OF

DIFFERENTIAL DIAGNOSIS OF MAIN SYMPTOMS

By Twenty Representative Contributors.

Edited by

HERBERT FRENCH, C.V.O., C.B.E., M.A., M D.Oxon,, F.R.C.P.

Consulting Physician to Guy's Hospital

This work is of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain It covers the whole ground of Medicine, Surgery, Gynaecology, Ophthalmology, Dermatology, and Neurology

Both authors and publishers deserve great praise for producing a volume which in substance brings the highest credit to British medicine and in format holds its own with the most lavish of transatlantic productions —BRITISH MEDICAL JOURNAL

The fund of knowledge contained in this volume is incalculable admirably illustrated —LANCET

Any question a *tour de force* will be found a friend in need at all times —PRACTITIONER

MEDICAL HYPNOSIS AND SUGGESTION

The following recent publications by EDWIN L. HOPEWELL-ASH, M.D., are now obtainable from BM/ELHA, London, W.C.1.

(1) THERAPY OF PERSONAL INFLUENCE: An ABC of Treatment by Personal Influence, Suggestion, Medical Hypnosis, and Psychomagnetic Methods. 2/9 postfree. Includes notes of 114 successful cases.
(2) AN ABC OF MEDICAL HYPNOSIS. 2/2 post free. Outlines simple methods—essentially practical.
(3) PSYCHOMAGNETISM AND PERSONAL INFLUENCE IN TREATMENT. A B.M.A. Address reprint; complimentary to Medical Practitioners.

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid close imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all repatable Instrument Dealers.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

Faulty Posture Should Be Corrected

High-heeled shoes, insufficient abdominal support, bad habits and "styles" of sitting and standing, occupational strain, and child-bearing, make lordosis posture exceedingly common among women of all ages and classes.

The woman who fails to see that the sway-back and sagging abdomen of lordosis posture are disfiguring is not likely to think of the deleterious effect of bad posture upon health.

Yet, doctors generally recognize that lordosis posture predisposes to enteroptosis and constipation. That it causes backache and headache. That it tends to create depression and other nervous symptoms. That it induces sacro-iliac strain. That in extreme cases it narrows the birth canal, both at the inlet and the outlet.

Orthopaedists agree that lordosis can be improved or corrected by improving postural habits, with the help of rest in bed, and by the wearing of a proper support.

Spencer Supports are designed to correct faulty posture. Each garment is especially designed and made to meet the needs of the person who is to wear it.

THE X-RAY REVEALS
the effect of incorrect posture

Fig. A.

Uncorseted figure—lordosis posture.

Note the sagging abdomen and the deeply curved back.

Correctly corseted with a Spencer.

Note the improvement in posture.

THE VITAMIN B_1 CONTENT OF LIVER EXTRACT

"The results suggest that those liver extracts which are rich in B_1 as well as in B_2 should be included in the list of medicaments available for use in cases in which administration of the vitamin B complex is indicated. Clinical evidence can indeed be adduced that such extracts are of practical value as general tonics, a fact which may be partly attributable to their vitamin content."

Extract from "The Lancet," June 27th, 1931, pp. 1423 and 1424.

LIVER EXTRACT (BOOTS) has been proved to be rich in both Vitamin B_1 and Vitamin B_2.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are two recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impetigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus. Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

BANTAM Coffee

Bantam Coffee is prepared from the finest selected Empire grown beans which are powdered and all the waste grounds extracted so that it dissolves instantly and completely when hot water or milk is added. A little Bantam Coffee dropped in a glass of warm milk makes a very palatable beverage. Bantam Coffee is absolutely free from adulterants and has been awarded the certificate of the Institute of Hygiene.

A 2/ tin yields 50 cups of delicious coffee.

A NON-HABIT FORMING ELIMINANT

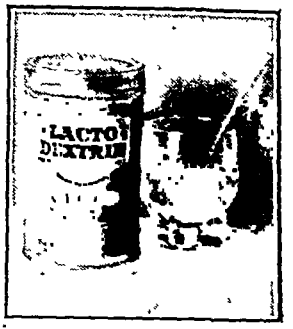
Sal Hepatica possesses all the essential qualities of the perfect purgative. Its action is prompt, painless and thorough. It is non-habit-forming, because it contains sodium phosphate which increases bile secretion—thereby avoiding the habit-forming propensities of other laxatives that call for steadily increasing doses. The exhibition of Sal Hepatica is by far the most pleasant and effective means of eliminating all toxic amino acids from your patient's system and ensuring regular defecation. Sal Hepatica is an efficient eliminant, antacid, cholagogue and diuretic.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol Myers Co.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal Hepatica

the proved, medicinal, saline laxative & cholagogue.



BRISTOL-MYERS COMPANY, 112, CHEAPSIDE, LONDON, E.C.2.

FAVOURABLE REPORTS *in clinical use of this combination of Lactose and Dextrin*

FURTHER reports have recently been received giving testimony to the value of Lacto-Dextrin as a food for changing the intestinal flora. Lacto-Dextrin is highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon.

Another important laxative agent for use in conjunction with Lacto-Dextrin is Battle Creek Psylla (psyllium seed). This emollient evacuant supplies both bulk and lubrication and is of special service in fissure and haemorrhoids.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, Ltd., 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

PSYLLA *(Psyllium Seed)*

LACTO-DEXTRIN

Products of the BATTLE CREEK FOOD CO., Mich., U.S.A.

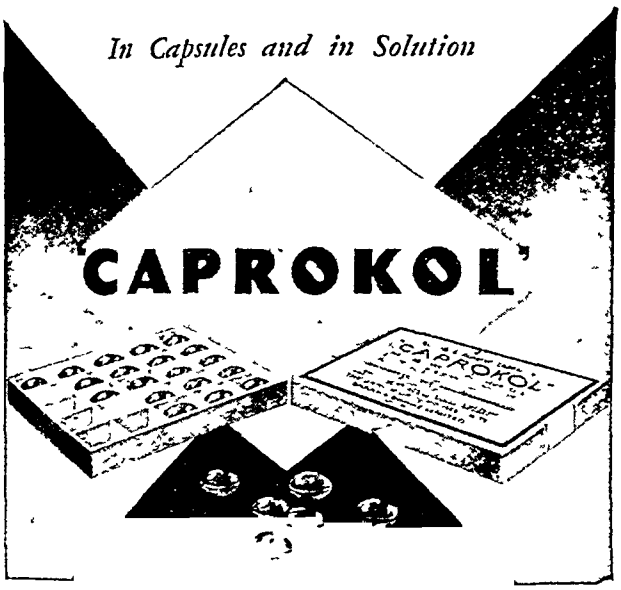
Effective Ferrotherapy

IDOZAN IS A COLLOIDAL IRON SOLUTION, NEUTRAL, AND CONTAINING 5 PER CENT. OF PURE IRON (Fe).

One teaspoonful of IDOZAN contains 25 ctgrms. of pure iron (Fe).
One dessertspoonful of IDOZAN contains 50 ctgrms. of pure iron (Fe).
One tablespoonful of IDOZAN contains 75 ctgrms. of pure iron (Fe).

Thus, by means of relatively small doses of IDOZAN it is possible—without any inconvenience to the patient—to give much larger doses of iron than could be accomplished with many of the older preparations. In cases of severe anaemia, for instance, one may very well give the patient one tablespoonful of IDOZAN three times daily. This dosage means a daily intake of 2.25 grams of pure iron.

Packings—8-oz. & 40-oz. bottles.



DOES NOT CONSTIPATE
DOES NOT DISCOLOUR THE TEETH
DOES NOT PRODUCE STOMACH DISCOMFORTS

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

Compound Syrup of Hypophosphites

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

Medisoaps

MIDGLEY'S MEDICATED SOAP

ACNE VULGARIS

The use of a suitable form of Sulphur in the pustular stage of Acne is generally effective in preventing the formation of indelible cicatrices. Several of the standard Medisoap exhibit active Sulphur both alone and in combination, and are ideal for the treatment of facial acne, and the greasy and scurfy condition of the scalp with which it is so frequently associated. The following Medisoaps are often prescribed by leading dermatologists for this purpose:

MEDISOAP No. 4	SULPHUR (Alkaline)
MEDISOAP No. 9	SULPHUR (Superfatted)
MEDISOAP No. 17	SULPHUR and RESORCIN
MEDISOAP No. 18	SULPHUR and NAPHTHOL

Several other formulae containing Sulphur are available. Full particulars with notes on their practical application are given in "Medisoap Therapy," a Prescriber's index to Medisoaps, which will be sent to members of the medical profession on application to:

Alimentary Toxæmia and Neurasthenia

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology

Intestinal Disinfection

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

THIS NAME GUARANTEES SAFETY

The name MARSHALL'S guarantees purity, efficiency, uniformity in every bottle of Lysol you purchase. There are other Lysols to be had, but MARSHALL'S is the only Lysol made to the original formula.

MARSHALL'S is better because it allows a greater margin of safety. In the correct dilution its bactericidal power is certain, yet it is harmless to the most delicate tissue. MARSHALL'S Lysol is the most widely used antiseptic for Obstetrics, Gynaecology, etc., because it is ideal for these purposes.

ONLY THE PUREST INGREDIENTS

All the ingredients of MARSHALL'S Lysol have to conform to the most rigid specification. Every stage of manufacture is subject to strict and constant supervision and analysis to ensure a product worthy of your recommendation.

Doctors, Nurses and Hospitals all over the world put their faith in MARSHALL'S—a faith that has been justified by 40 years of unfailing efficiency and uniformity.

Sample free on request to members of the medical and nursing professions.

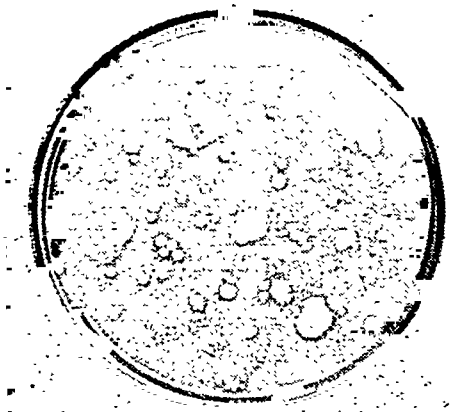
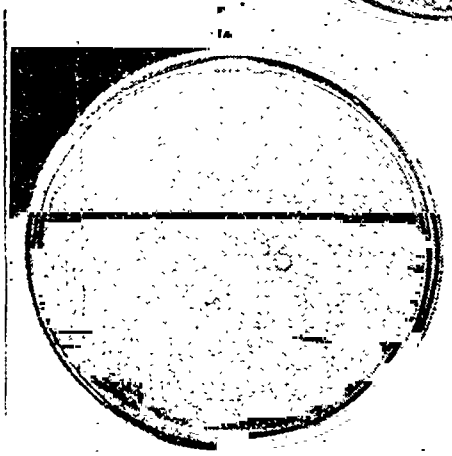
Streptococcal Conditions

In the treatment of streptococcal conditions Vaccines provide the surest means of reaching deep-seated organs which are inaccessible to antiseptics. Some practitioners, however, are deterred from using Vaccines owing to fear of reactions, but this objection may be overcome by employing Detoxicated Streptococcal Vaccine (Genatosan). In the preparation of this vaccine all the toxic elements of the germ are removed; as a result it is given in both acute and chronic cases without harmful reactions and produces a high degree of immunity.



For the average case a course of five injections is recommended, commencing with an initial dose of 1,000 millions and working up to a maximum of 20,000 millions. Detoxicated Streptococcal Vaccine is polyvalent and is suitable for the treatment of septicæmia, puerperal fever, cellulitis, lymphangitis, and all septic infections of streptococcal origin.



Practitioners interested in Vaccine Therapy are invited to write for a brochure covering the full range of Detoxicated Vaccines, to Genatosan Ltd. (Vaccine Dept.), Loughborough, Leics.

BETTER MILK FOR BABIES

ORDINARY MILK

1/1,000 c.c. plated—over 200,000 bacteria per c.c.

LACTOGEN
Full strength mixture.

1/10 c.c. plated—less than 100 bacteria per c.c.

FACTS ABOUT LACTOGEN

Purity

Lactogen is under hygienic and scientific control from the time the raw milk is collected until the despatch of the finished product.

The fresh milk used for its preparation is obtained from selected farms, the herds receiving close supervision from the Company's farm inspectors.

A stringent examination is also carried out in the factory laboratory, and with these precautions a constant high degree of purity is maintained.

The modern manufacturing process is carried out under the most strictly hygienic conditions, and the bacterial count of Lactogen, as reconstituted, is less than 100 organisms per c.c.

Lactogen is prepared in England by Nestlé's—famous for more than fifty years for the purity of their milk products—from the pure, fresh milk of specially selected herds, grazing on picked English farms.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

FREE SAMPLES with detailed descriptive literature will be sent to any Member of the Medical Profession upon request.

BETTER MILK FOR BABIES

A NEW PREPARATION

COLLOSOL CALCIUM
WITH
VITAMIN D
ORAL

THIS new Collosol preparation containing 1% (approx.) of a colloidal calcium salt of the fatty acids of cod liver oil is standardised to contain 250 M.R.C. units per teaspoonful of Vitamin D, in the form of irradiated Ergosterol (Pat. 236197/24) equivalent in Vitamin D to half a teaspoonful of the finest cod liver oil.

Modern biochemical science has shown that utilisation of calcium, when absorbed from the intestinal tract is largely a function of Vitamin D. Normally this accessory food factor is present in a well balanced diet, and is present in some natural oils. It is to this factor that cod liver oil owes its antirachitic properties.

Rats fed on a deficiency diet inducing rickets can be cured in a few days by the administration of Collosol Calcium with Vitamin D. Rachitic rats when *injected* with Vitamin D are practically unaffected whilst controls given the same doses *orally* are rapidly cured. It should be noted that the oral route is the natural method for administering vitamins.

WHERE THE LABORATORY COUNTS

BECAUSE Sunshine Glaxo incorporates all qualities that infant specialists consider essential in a milk-food intended to replace or to supplement breast-feeding, its use is unattended by the difficulties that commonly beset the artificial feeding of infants.

Above all, special attention has been paid to the vitamin and mineral balance. After prolonged and carefully controlled clinical trial, we have found the optimal amount of vitamin D that must be added to ensure adequate assimilation of calcium and sound bone development; and the exact modification in the mineral content, especially of iron, that must be made to bring about a healthy growth of the whole infant organism.

Especially during the summer months, when bacterial purity and easy digestibility are more than ever essential in infant food, is the use of Sunshine Glaxo the best possible safeguard against the gastro-intestinal infections and disturbances of artificially fed infants.

SUNSHINE GLAXO

We should be glad to send a trial supply to you or your patient. Send a postcard to GLAXO LABORATORIES : 56 OSNABURGH STREET : LONDON N.W.1.

An Address
ON
STATURE AND POSE
THE PROBLEM OF UNEQUAL LEGS*

BY

ERNEST W. HEY GROVES, F.R.C.S.
PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL

"Which of you, by taking thought, can add one cubit unto his stature?"

I suppose that if this question was propounded for our answer to-day we should devote ourselves almost entirely to a consideration of the possibility of provoking endocrine stimulation of the pituitary gland. A cubit is the distance from the tip of the elbow to the tip of the middle finger, and is about 18 inches in a full-grown adult. The true acromegalic giants, such as Charles Byrne, John Hunter's famous trophy, may be more than two feet taller than an average adult, and if we knew how to add to the bulk or to increase the activity of a normal pituitary gland such an addition to the stature of a growing adult might easily be made.

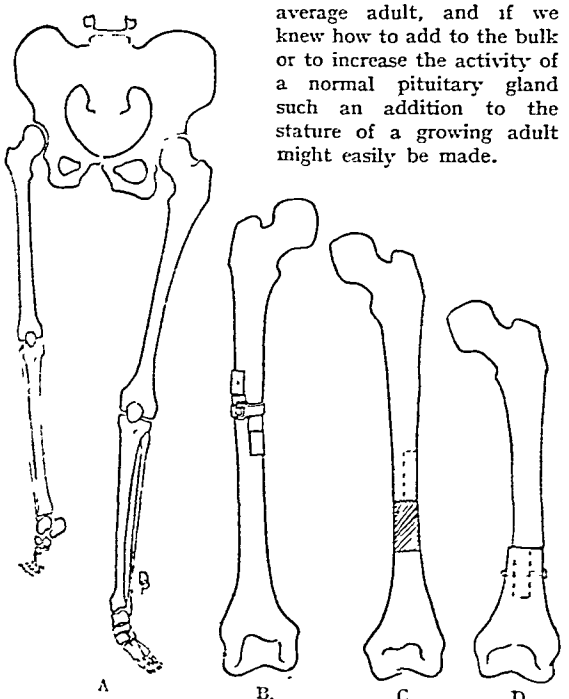

FIG. 1.—Shortening of the leg due to infantile paralysis. A. Outline of the limbs showing intrinsic shortening of right femur. B. Method of lengthening femur; step-cut and grafts. C. Method of lengthening femur. D. Shortened femur after impaction. (In the actual case the peg is made from the lateral half of the femur, whereas in practice it is formed from the posterior half.)

A man's height depends chiefly on the length of the spine, the femora, and tibiae. The length of the spine is made up of the thickness of twenty-four vertebral bodies (cervical, dorsal, and lumbar) and of twenty-three intervertebral disks, but the total length of the vertebral column will vary with its curvature. Any marked variation from the normal affecting the stature is always

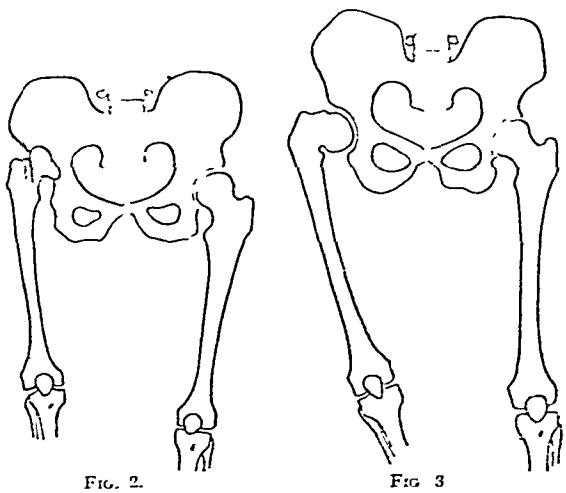

FIG. 2. FIG. 3

FIG. 2.—Congenital dislocation of the hip in an adult.
FIG. 3.—Coxa vara with characteristic adduction deformity.

in the direction of shortening. Thus in the classical case of Sir James Paget's first patient with osteitis deformans, the man, who had been an officer in the Guards, 6 feet 2 inches in height, became so bent and bowed in later life that he measured only 5 feet 8 inches. It is commonly believed that a young adult can actually, but temporarily, increase his height by about a half to three-quarters of an inch simply by remaining recumbent for about a week. This attitute is supposed to allow each intervertebral disk to increase in thickness by a fluid accommodation in its nucleus pulposus. This half-inch may be of vital importance to a man measuring 5 feet 11½ inches, if he wishes to enter a regiment of the Guards.

I do not propose, however, to discuss these rather fascinating questions of general skeletal growth or of spinal length, but to devote myself to the very important and practical problems of the balancing of a patient on legs of unequal length, or alternatively of making those legs equal.

This problem presents itself in four common groups of cases—namely, malunion of fractures (usually of the femur); faulty ankylosis of the hip-joint after infective arthritis; poliomyelitis; and congenital dislocation of the hips. In these cases there may be actual shortening of a bone such as the femur. It may have been broken and then united with several inches of overlap, or in the paralytic cases (Fig. 1, A) the femur may have failed in its normal growth. The shortening may be due to the dislocation of the hip—congenital (Fig. 2), traumatic, or pathological—the head of the femur lying one or more inches above the level of the acetabulum. Again, shortening may be caused by the adduction or varoid angulation (Fig. 3) in the shaft or neck of the femur or actually in

* An address delivered before the Royal Free Hospital Medical Society.

the hip-joint. The shortening effect of this deformity is due chiefly to the fact that in order to achieve parallelism of the legs, the pelvis must be tilted up on the affected side.

Before discussing the best way of treating a case in which the legs are of very unequal length, it may be

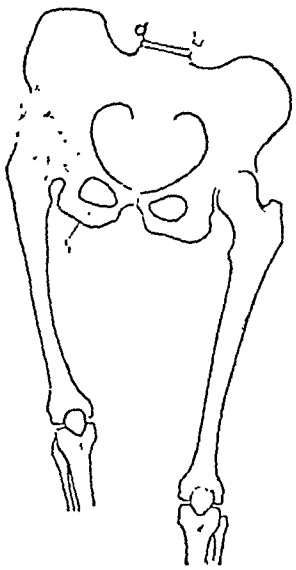

FIG. 4.

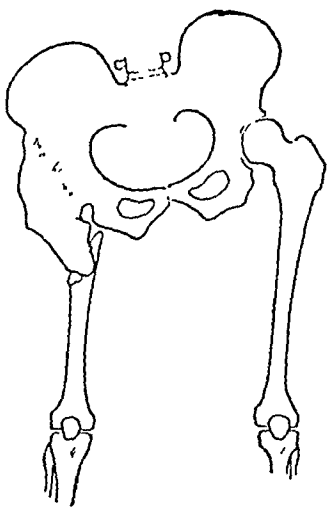

FIG. 5.

FIG. 4.—Ankylosis of hip in marked adduction.

FIG. 5.—*Bifurcation osteotomy, which, by correcting the adduction deformity, effectually lengthens the leg in condition shown in Figs. 2, 3, and 4.*

useful perhaps to say a word about prophylaxis. There is no pious precept so often repeated, and yet so often ignored, as that "prevention is better than cure." Probably gross deformity could have been prevented by timely treatment in more than half the cases which present themselves. At the present day there is no justification for allowing a fracture of the femur to unite in such a way as to cause an appreciable shortening. In this connexion it should be borne in mind that callus union is soft and plastic, and that if a femur is half an inch short at the end of six weeks, it will probably be an inch shorter at the end of six months, owing to the yielding of callus to pressure or to the increase of an angular deformity if insufficiently splinted. The greatest crippling deformity, however, is produced by the slow, insidious, infective arthritis of the hip if vigilance is relaxed in the early days. The thigh becomes flexed and adducted, and, when fixed in this position, the effective length of the leg is reduced many inches by the tilting of the pelvis necessary to get one leg in the same line as the other (FIG. 4). All that is required is to fit the child on to a proper frame in the early months in order to secure a much smoother and less painful course for the disease, and to prevent any crippling deformity.

TECHNIQUE OF DIRECT LENGTHENING OF BONES

While it may be unnecessary to dwell at length on the technical details of methods of bone lengthening, I should like to give a short review of commonly advocated methods in order to indicate their relative advantages and disadvantages.

The Use of Transfixion Pins

The use of rigid transfixion pins seems to me to be almost an essential element for any effective method of skeletal traction. I use only two sizes (3/16 inch by 6 inches, and 1/8 inch by 4 inches), and in rare cases when I have to deal with a child's olecranon or a phalanx I improvise a small pin from a steel knitting needle. I would always carry out the transfixion under a general anaesthetic, not because the pain of perforating the limb cannot be abolished by local injection, but because under a general anaesthetic a strong traction of 200 lb. or more can be used for a few moments; another reason is that during the first hours of traction (by 40 or 50 lb.) the muscles will be fully relaxed. When the pin has perforated the limb a pulley-bearing clamp is fixed on it; with a pulley block at the foot of the bed this allows a strong and steady traction to be exercised by a weight which may be multiplied up to four times according to the number of pulleys used. Thus with a 10 or 15 lb. weight, a 40 or 60 lb. pull is obtained. Such a powerful traction will, of course, necessitate raising the foot of the bed and also fixing a counter-extension perineal band round the opposite thigh, this being tied to the bed head.

I would urge that this use of the transfixion pins affords the maximum of simplicity combined with efficiency. The so-called ice-tongs callipers, which have rightly been discarded, gave no advantage which compensated for the real danger of their slipping or dragging if used for any effective weight extension.

Hawley's Table

Transfixion pins, however, can be utilized in other ways. Hawley's table, of which there have been many modifications, is in my opinion a necessary part of most of the traction operations or fracture methods, enabling one or both legs to be fixed at any angle and pulled upon by a very powerful screw appliance. The efficacy of this screw traction will be greatly increased if one or more transfixion pins have been passed through the limb and the screw pull applied directly to the pin. The desired amount of traction and lengthening can be fully maintained by a plaster bandage, applied while the patient is still on the table. Thus in a neglected or malunited fracture of the femur, with 3 inches of shortening and angulation, a pin was passed through the supracondylar region of the femur, and the leg, pulled out to full length on a Hawley's table, put in plaster; the transfixion pin being left in place three weeks and then removed without disturbing the plaster. The possibility of combining the use of a Hawley's table with transfixion pins opens up very great chances of rapidly and completely correcting certain deformities and of lengthening shortened legs. In many cases of malunited fracture with much shortening

A. B.

C.

FIG. 6.—Case of ankylosis of the hip in adduction. A Before bifurcation operation. B After bifurcation operation. C Five inch-raised shoe worn before operation.

a careful choice will have to be made between the two methods of (1) full or immediate lengthening done by a Hawley's table and fixation by plaster over transfixion pins, and (2) gradual traction by weight and pulleys. Probably in a difficult case the maximum of efficiency and accuracy will be obtained by first breaking down the malunited fracture, then applying skeletal traction for six to ten days, and lastly giving a final adjustment on the Hawley's table and fixing in plaster.

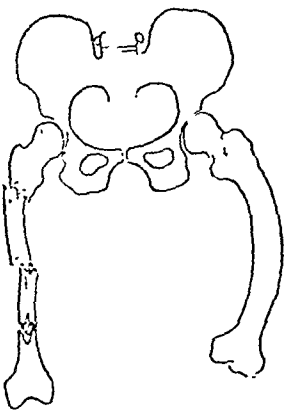

FIG 7.—Gross curvature of the femora due to rickets, treated by multiple osteotomy.

Double Transfixion Apparatus

Another appliance for lengthening bones is the double transfixion apparatus, which I designed, and used frequently in 1914 and succeeding years. Its principle depends on the transfixion of the broken bone at two points near the extremities. The projecting ends of the rigid steel pins are engaged in a frame, consisting of side bars and a circular band, which allows distraction to be made by a screw action and fixation in any relative position of rotation of one fragment upon another. This apparatus, or one similar to it in principle, has been invented independently and described by many surgeons, and it appears in most of the large works dealing with the treatment of fractures. I never use the apparatus now, because I find that the combination of skeletal traction with the Hawley's table, followed by plaster fixation, gives just as good results with much less pain to the patient.

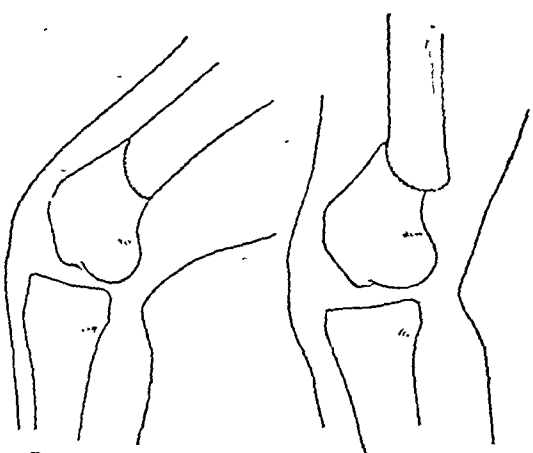

FIG 8.—Contracture of the knee causing shortening, treated by curved osteotomy.

The Wire Method

The modern vogue for skeletal traction now rather favours the use of taut steel wire, generally known as Kirschner's wire, though many surgeons have suggested its use and invented a technique for its application. The essentials of the wire method are as follows: A rigid piece of hard, rustless steel wire, 1 to 2 mm. thick and about 30 cm. long, sharpened at one end, is held in a motor or other mechanical drill stock, and is made to pierce the leg; this it does with great ease and rapidity. To prevent the wire from bending under the pressure, it is held in a collapsible concertina clamp. When the steel wire has traversed the limb, including the bone, its two projecting ends are engaged in a very strong steel horse-shoe clamp, one end being screwed tightly and the other remaining loose. The loose end is then pulled as tight as possible by a special steel screw, which is fixed in this taut position. Weight is now attached to the horse-shoe and traction carried out in the ordinary way. It is claimed for this method that it is never followed by a septic bone sinus. But there are two arguments against it: one is that if it is used for the application of a heavy weight, it is likely to be dragged through the bone, especially if this is at all decalcified; the other is that the technical difficulties of the method hardly justify its use in any except very large fracture clinics. In the method of its application it complicates the use of skeletal traction.

THE LENGTHENING OF AN UNBROKEN BONE

So far I have considered only the question of increasing the length of a broken bone, which usually consists in restoring it to its original measurement; but in many cases of marked inequality of the legs, especially in poliomyelitis and tuberculous hip disease, there may be a possibility of lengthening the short leg. This problem involves several considerations beyond the merely mechanical one of bone lengthening. The short leg in these cases is nearly always under-nourished, with poor blood supply, weak muscles, and slender bones. As the limb is therefore ill adapted to plastic operations, it is much wiser, in my opinion, to shorten the sound leg rather than attempt to lengthen the weak one. The patient, however, may readily consent to any operation on the "bad leg," but will be very reluctant to have the good leg interfered with. In such circumstances what are the possibilities of the method? Various ingenious appliances have been designed for bone lengthening, all of them having the essential design of a double transfixion apparatus with external screw distraction rods. I am not convinced that there is any apparatus that will produce more favourable results than can be obtained by immediate traction on a Hawley's table, or, better still, by skeletal traction making a steady pull on the divided bone. The femur must be divided either by a long oblique division or by a shaped osteotomy. If immediate lengthening is made, suitable bone wedges are placed in position and the bone united by a band (Fig. 1, B). If continuous traction is used, a transfixion pin is passed through the lower end of the femur and weight traction carried out while the knee is kept flexed. The actual limit of such lengthening of the bone is about 10 per cent.

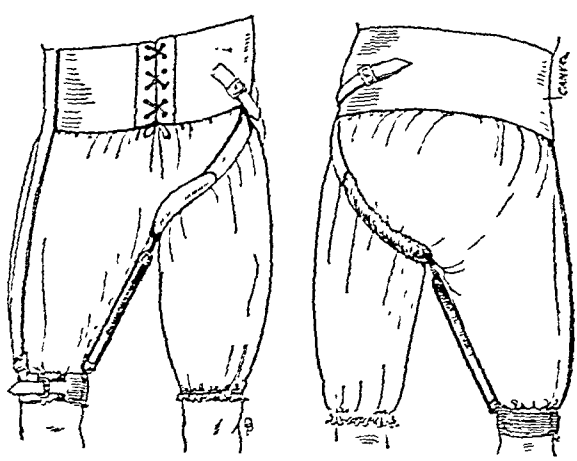

FIG 9.—Ambulatory abduction splint to be worn for six months after bifurcation osteotomy.

—that is, about one and a half inches to a fifteen-inch femur, so that at the end of a rather difficult and hazardous procedure the maximum gain is not very great.

THE LENGTHENING OF A CURVED BONE

Apart from bones which have been shortened by malunited fractures, there are many cases of legs shortened and deformed by curving of the bones or by contracture of the knee. Such conditions result from various types of rickets and also from infection or paralytic conditions of the knee with flexion contracture. A grossly distorted femur usually has two pronounced curves (Fig. 7), one outward just below the trochanters, and the other forwards, below the middle of the shaft. The best operative correction of this double deformity is a double or triple osteotomy followed by continuous weight traction. The osteotomy should aim at splintering the bone obliquely at the points of maximum curvature, and is best done by a hammer and chisel. When both femora are affected, as in the case depicted, I think it is wiser to deal with one leg at a time, allowing sufficient interval (about six months) for the first leg to become firm and sound before touching its fellow. In the case of a contracted knee-joint which is free from intrinsic adhesions and allows of flexion but cannot be fully extended (perhaps by 20 degrees), it is easy to restore complete extension to the joint without interfering with its mechanism (Fig. 8). A curved osteotomy is performed just above the condyles, the curved cut being as nearly as possible parallel to, and concentric with, the curve of the condyles. This is done by means of a band-saw or a fretsaw through two lateral incisions just behind the quadriceps muscle. When the bone has been divided, the knee can be fully straightened and put up in this position in plaster.

SLIPPED FEMORAL EPIPHYSIS AND EARLY COXA VARA

There is, I think, a mistaken notion held by students and practitioners that coxa vara, resulting from a slipped epiphysis of the head of the femur, is a condition that should be left alone until growth is at an end, and then corrected by an osteotomy. This view is certainly quite wrong. The slipped epiphysis can be corrected by manipulation within several weeks of the onset of the deformity, and, at a later date, when the neck of the femur is being remoulded to form a coxa vara, it can still be fully corrected by a single operation which will result in a perfect hip, six months only being required for the correction treatment. If full growth is allowed to occur, with the establishment of coxa vara, the patient is incapacitated by a crippled condition for years, and operative correction is merely palliative. Within a few weeks of the occurrence of slipping of the epiphysis, correction can be done by forcible manipulation, the leg being put up in full abduction with internal rotation in a plaster spica. At a later stage an operation is necessary to divide the femoral neck, and then, when complete restitution has been carried out, the head of the bone is fixed by a bone nail driven into it from the trochanter.

THE BIFURCATION SUBTROCHANTERIC OSTEOTOMY

The shortening and deformity in many unequal legs are due to a faulty relation of the bones at the hip-joint, either actual dislocation or more often adduction with flexion deformity by which the pelvis has to be tilted up on the diseased side in order that the legs may be parallel. It is the general rule that in dislocation, arthritis, or ankylosis of the hip, the limb becomes fixed in adduction and flexion, so that to the real deficiency is added a much greater functional shortening—unfortunately called "apparent." Thus the affected limb in cases of faulty ankylosis of the hip and in congenital dislocation is often 4 to 6 inches off the ground in the standing position (Figs. 2 and 4). This apparent, or as it should be called, functional shortening, is measured by taking the length from the upper border of the symphysis pubis to the tip of the internal malleolus. It has always been recognized that this great functional shortening due to adduction and flexion of the hip should be corrected by a subtrochanteric osteotomy. In recent years Lorenz has elaborated the idea that this osteotomy should aim, not merely at altering the angle of the femur, but at making a sort of fork at its point of contact with the pelvis. This is known as the bifurcation osteotomy (Fig. 5). I have done this operation many times, but I am doubtful if the making of a fork at the top of the femur really achieves much more than the old-fashioned simple osteotomy. Three things are gained by a subtrochanteric osteotomy in these cases of adduction deformity of the legs. In the first place, by abducting the femur and fixing it in this position the pelvis will come to be tilted down on the diseased side when the legs are parallel. Thus functional lengthening will be made to counteract real shortening. In a typical case (Fig. 6) the diseased leg is 1½ inches shorter than the sound one, and the adduction deformity makes the pelvis 2 inches higher on that side than on the other; there are therefore 3½ inches of functional shortening. After osteotomy and abduction the anterior superior iliac spine is brought down to a level 1½ inches below its fellow, and this exactly counterbalances the 1½ inches of real shortening, so that, as the patient stands, the two legs are apparently of the same length, the pelvis being inclined downwards on the side of the diseased limb. In the second place, the axis of the femur comes to lie under the line of weight of the body, instead of lying quite outside it. In other words, the weight of the body is transmitted direct to the femur instead of hanging on to its side. Thirdly, there is provided a wide area of contact between the pelvis and the upper end of the femur by which the body weight is transmitted. The operation is a very simple one. The femur is cut down upon through an internal incision over the base of the great trochanter, and the bone is divided by an oblique saw-cut, which runs downwards and backwards. When it has been completely divided, the shaft of the femur is forcibly abducted and then pushed in towards the symphysis. The degree of abduction in which the leg is fixed must be decided upon beforehand, and is determined by the amount of tilting of the pelvis which has to be corrected or over-corrected. The body and leg are fixed in a plaster spica, which is maintained for six weeks and is then renewed as a short spica down to the knee for another six weeks. Then for six months the patient must use either a walking calliper splint or some form of ambulatory abduction splint. For the latter I have found the appliance illustrated by Fig. 9 very useful. It is very light and can be worn outside the underclothes concealed by the dress or trousers. It is very important to provide in this way against the occurrence of adduction, which is liable to be brought about by the excessive pull of the adductor group of muscles acting on the bone while it is still soft.

LENGTHENING THE LEG BY THE EQUINUS POSITION

One of the most natural attempts to make good a shortened leg is by walking on tip-toe, and this attitude is therefore assumed by every patient who has a short leg. How far should this practice be allowed or encouraged? It is quite certain that it is unsatisfactory for a patient always to walk on tip-toe with the heel off the ground. The attitude involves constant strain on the calf muscles with consequent fatigue, and this will be all the greater as the muscles are already weakened by partial paralysis. The heel, therefore, must be supported by raising that part of the boot. In an adult foot measuring 7 inches from the heel to the ball of the great toe, the following

angles of tilting will be associated with the corresponding *raising* of the heel—namely, 15 degrees tilting with 1½-inch heel; 30 degrees with 3½-inch heel; and 45 degrees tilting with 5-inch heel. But even if the heel of the foot is supported by a raised heel of the boot, the pose of the foot is not very satisfactory, because the calf muscles are thrown out of action to an extent measured by the degree of tilting of the foot, and the patient loses spring and resiliency of step. Probably 15 degrees of tilting is the maximum advisable, representing a gain in height of about an inch, since the other shoe must have a heel of at least three-quarters of an inch. Both instrument makers and surgeons, however, have gone much beyond this limit, and have tried to convert the foot into an extreme equinus position. A special type of boot is widely advertised in which the heel is 5 or 6 inches off the ground, the equinus position being masked by making this elevation of the heel inside the boot. Such an appliance does disguise the deformity, but it does so at the expense of the muscular balance of the leg. In the same way the Mikulicz operation, by which the os calcis and astragalus are removed and the rest of the tarsus and metatarsus brought into a straight line with the tibia, results in a gain of about 5 inches in the length of the leg, but the limb, in consequence, is much less useful for walking than an artificial limb would be. There is an interesting specimen in the Museum of the Royal College of Surgeons representing the leg and foot of a girl, aged 18, on which the Mikulicz operation had been performed by Sir William MacCormac. The patient had infantile paralysis with paralytic equinus, and the leg was amputated by Sir John Bland-Sutton owing to the pain and uselessness of the limb, in spite of the fact that perfect bone union had occurred in good line. It may therefore be laid down as a definite rule in dealing with a weak, short leg, that a plantigrade position of the foot should be preserved, or certainly not departed from by more than 15 degrees of tilting.

SHORTENING OF THE SOUND LEG

For equalizing the length of legs another valuable device, which I think is not resorted to as often as it might be, is the shortening of the longer leg. In the majority of cases we are considering, whether tuberculous hip disease, infantile paralysis, or congenital dislocation of the hip, the long leg is strong and has good sound bones with perfect muscular and vascular supply. In such a leg the femur may be shortened with perfect impunity by 25 per cent. of its total length—that is, in the adult about 4 inches. I have done this operation in various ways, by taking a piece right out and uniting the shaft over a peg, or by a "step-cut" operation, but I now use an impaction method, which is much simpler than either of these (Fig. 1, C and D). If, for example, 4 inches is to be taken from the femur, the bone is exposed by a lateral longitudinal incision in its lower part about 6 inches long. The muscles are divided between the rectus and the vastus externus, and the bone is sawn through about 2 inches above the condyles. The shaft is brought out of the wound and 2 inches are cut off. The remainder is removed by a longitudinal saw-cut 2 inches in length, passing from side to side, the anterior part being cut away, leaving the posterior part of the femur, including the linea aspera, sticking out. This is trimmed by the saw and chisel into a peg about half an inch thick. The lower fragment of the femur is bored by a twist drill of suitable diameter, and the upper fragment is then impacted into it, and fixed in place by a single transverse ivory nail. It is very remarkable how the slack of 4 inches of muscle is taken up within a few months and the full muscular power of the leg regained.

Two examples will suffice to illustrate the possibilities of this method.

CASE I

A woman, aged 25, had a long-standing infantile paralysis with dislocation of the hip on the same side. When she came to me the left leg was 5½ inches off the ground, caused partly by tilting of the pelvis and partly by insufficient growth of the leg, which was encumbered by a heavy apparatus consisting of a calliper splint and high boot. I did three operations. First, the left flail foot was stabilized by a partial tarsectomy (Naughton Dunn's operation), so that she could get firm plantigrade stance without irons; secondly, an osteotomy was performed below the left trochanter, so as to bring down the pelvis on the left side, lengthening the leg by 1½ inches and allowing her to support her body weight direct on the femur, instead of hanging it on to the capsule of the dislocated joint; thirdly, six months later, the right femur was shortened by 4 inches, thus bringing her two legs to the same length. She can now walk on limbs of the same length, and for the first time in her life she can wear an ordinary pair of shoes.

CASE II

A man, aged 30, who must have had osteomyelitis of the upper end of the right femur in childhood, came to me wearing the largest "surgical" boot I have ever seen. It was 9 inches high at the heel and weighed 7 lb. He was sent to me for amputation, and it was obvious that an artificial limb would have been much more serviceable to him than the horrid boot. He had, however, an adduction and flexion deformity of the hip-joint, and this would have had to be corrected even if an amputation had been done. He gladly consented to a series of reconstructive operations, by which his own foot and leg have been preserved. An osteotomy was performed below the neck of the left femur, and the leg put up in abduction. This gained 2 inches for the functional use of the leg. The right leg was shortened by 4 inches, and his two legs are now within 3 inches of the same length. He was so pleased with this result that he is now trying a boot raised 3 inches at the heel and 1½ inches in the sole, postponing for the present a possible bone-lengthening operation on the left femur.

As the result of the active campaign that is being carried out to-day for the treatment of crippled children there are fewer of these cases of adult gross deformity than formerly; but there will always be a sufficient number to make the problems involved of great practical importance.

A CASE OF PERNICIOUS ANAEMIA RESISTANT TO TREATMENT

BY

A. M. KENNEDY, M.D., M.R.C.P.

PROFESSOR OF MEDICINE, UNIVERSITY OF WALES, AND DIRECTOR OF THE MEDICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

A civil servant, who had always lived a temperate life in this country, at the age of 52 noticed that he was becoming pale and rather easily tired, and a year later, on account of these symptoms having become worse, he spent a month at a convalescent home on the South Coast. Shortness of breath and palpitation on exertion began to trouble him; sleep did not come easily at night; and six months after returning home his doctor told him that he was suffering from pernicious anaemia, and prescribed from a quarter to half a pound of liver daily. He did not seem to make any progress, however, either for better or for worse; and after six months' treatment with liver daily he was admitted to hospital under my care.

He was then 54 years of age, a well-nourished man, 11 st. 10 lb. in weight, with fairly considerable subcutaneous fat. His skin and mucous membranes were pale, the former possessing the slight lemon tint so typical of pernicious anaemia. He had been treated for an appendix abscess at the age of 48, but had had no other illness before the onset of the complaint from which he was now suffering. His appetite had always been good, and he had not suffered from vomiting, diarrhoea, or from troublesome constipation.

A haemic murmur was audible at the base of the heart, but nothing further of note could be made out on examination of his chest. The liver was not enlarged, and the spleen was not palpable below the costal margin, nor was the splenic dullness found to be increased on percussion. He complained of slight tenderness on deep palpation in the left iliac fossa, where, through a resisting abdominal wall, a small though rather indefinite sausage shaped mass seemed just palpable along the course of the colon. On inquiry he stated that for some years he had passed at varying intervals a little mucus on defaecation, especially if he had allowed his bowels to become constipated. Examination per rectum revealed a few small haemorrhoids only. His teeth were all artificial, his tongue was moist and clean, smooth, but free from any soreness, and he did not admit to having suffered from a sore tongue previously. No enlarged glands were present anywhere, his arteries were not thickened, and the Wassermann reaction of his blood was negative. Blood examination on admission to hospital (April 25th, 1930) revealed the typical picture of pernicious anaemia, as follows:

Red cells, 1,030,000 per c mm ; white cells, 2,000 per c mm ; haemoglobin, 28 per cent. ; colour index, 1.4 , platelets, 61,000 per c.mm. Red cells well stained and filled with haemoglobin, showing marked variation in size and shape ; numerous megalocytes and microcytes present, and an occasional megaloblast ; reticulocytes found only after prolonged search. Polymorphonuclears, 45 per cent. ; eosinophils, 1 per cent. ; lymphocytes, 46 per cent. ; large mononuclears, 8 per cent.

The patient was then put to bed and given, in addition to the ordinary hospital diet, half a pound of lightly cooked liver and one orange daily for the next two months, and his blood was examined regularly at weekly intervals His general condition remained much about the same, and any improvement that occurred in his blood was practically negligible. On one occasion only the reticulocytes rose to 2 per cent. ; on all other occasions they were much fewer, and found only after prolonged search At the end of two months' liver treatment examination of the blood showed (June 20th):

Red cells, 2,070,000 per c mm. ; white cells, 4,200 per c mm , haemoglobin, 38 per cent , colour index, 0 91 ; platelets 42,000 per c mm Red cells well stained, with some variation in size and shape, some larger and others smaller than normal, but no nucleated reds obvious. Reticulocytes found only after prolonged search.

In view of the fact that the patient had had from a quarter to half a pound of liver daily for the six months before coming into hospital, and that, after admission to hospital, two months' treatment with half a pound of liver daily produced an increase in the red cell count of only one million per c mm (the highest count being no more than 2,070,000 per c mm), with less effect on the other constituents of the blood and with practically no effect on the reticulocytes, it was concluded that the case was resistant to liver therapy. (The changes in the blood occurring at weekly intervals during the two months when the patient was undergoing liver treatment in hospital are shown in the first part of Chart 1) The liver was thereupon stopped, and the patient given desiccated extract of stomach tissue in the form of ventriculin for the next three and a half months. The contents of three tubes of ventriculin (= 30 grams) were given daily in one dose, and the blood was examined regularly at weekly intervals. A week after the treatment with ventriculin was commenced the examination of the blood showed (June 27th):

Red cells, 1 670,000 per c mm. ; white cells, 2,000 per c mm , haemoglobin, 33 per cent , colour index, 0 99 , platelets, 31 000 per c mm Red cells well stained, with some variation in size and shape, some larger than normal and some smaller, but no nucleated reds seen , reticulocytes found only after prolonged search.

About two and a half weeks after starting on the ventriculin treatment the patient began to pass a little blood (approximately half an ounce) in the stools, and also some mucus This continued almost every day for a fortnight. He caught a cold, herpes appeared on his lips, and his general condition seemed to get much worse. This was confirmed by the blood examination, which showed (August 22nd):

Red cells, 720,000 per c.mm. ; white cells, 2,200 per c mm ; haemoglobin, 21 per cent. ; colour index, 1.4 , platelets, 13,680 per c mm. Red cells well stained, with marked variation in size and shape; numerous megalocytes and microcytes; no nucleated reds seen, and reticulocytes found only after prolonged search.

On account of this very serious deterioration in the patient's condition it was decided to resort to blood transfusion, and two days later he was given about ten ounces of blood intravenously. There was some general reaction immediately following the transfusion, but five days later he seemed rather better, his colour had improved, and blood examination revealed (August 29th):

Red cells, 1,220,000 per c mm. ; white cells, 1,600 per c.mm. ; haemoglobin, 22 per cent. ; colour index, 0 9 , platelets, 24,000 per c.mm. Red cells well stained, varying in size and shape; many megalocytes and microcytes present, no nucleated reds seen, and reticulocytes found only after prolonged search.

His cold improved, and the passage of blood in the stools ceased after the transfusion, but a little mucus continued to be passed. He was given a second blood transfusion (11 oz.) a month after the first, and shortly before the end of the course of ventriculin, and no general reaction followed. At the end of the three and a half months' ventriculin treatment blood examination revealed (October 3rd):

Red cells, 1,420,000 per c.mm ; white cells, 3,600 per c.mm. ; haemoglobin, 34 per cent ; colour index, 1.1 ; platelets, 29,820 per c mm. Red cells well stained, with marked variation in size and shape ; megalocytes and microcytes present ; no nucleated reds and no reticulocytes found after prolonged search.

The weekly blood examinations failed to show that the ventriculin had at any time produced even the slightest improvement in the blood, and reticulocytes were always difficult to find. The changes in the blood, as they occurred at weekly intervals during the three and a half months when the patient was undergoing ventriculin treatment, are shown in the second part of Chart 1.

It was thus obvious that the ventriculin treatment was useless, even though it had been reinforced by two blood transfusions ; and as previous liver treatment had also failed, the case presented a difficult problem. The presence of tenderness and of an indefinite small sausage-shaped mass palpable with difficulty in the left iliac fossa, associated as it was with the passage of mucus and some blood in the stools (even though small haemorrhoids were present), added to one's anxiety lest a carcinoma be present. Radiological examinations after a barium meal and a barium enema showed on one occasion some indefinite narrowing at the site, which a subsequent investigation did not confirm.

After consideration it was thought, on the whole, probably wiser to clear up the question by exploratory laparotomy. This was done (October 9th) by my colleague Mr. Lambert Rogers. Some adhesions were found round the caecum (the appendix had been removed six years previously), but no tumour was present in the colon or elsewhere, and none of the other viscera showed any abnormality. The abdominal wound healed quickly, except for a stitch abscess, which continued to discharge for about three weeks Twelve days after the laparotomy, and twenty-one days after a blood transfusion, examination of the patient's blood showed (October 21st):

Red cells, 2 200 000 per c mm , white cells, 3,900 per c mm , haemoglobin, 41 per cent , colour index, 0 9 ; platelets, 37 000 per c mm Red cells well stained, marked variation in size and shape , megalocytes and microcytes ; no nucleated reds, and reticulocytes found only after prolonged search

Ten days after this the blood count was (October 31st):

Red cells, 1,140 000 per c mm ; white cells, 4 200 per c mm , haemoglobin, 30 per cent , colour index, 1 3 ; platelets, 31,200 per c mm. Films no change from preceding examination.

Koessler, Maurer, and Loughlin,[1] as the result of observation and experiments on rats, suggested that chronic vitamin deficiency (A, B, and C) might play a part in the production of pernicious and other severe anaemias, and that vitamin A in the diet was essential to blood regeneration. It was therefore decided to try multiple vitamin therapy in this case.

The patient was given vitamins A and D in the form of radiostoleum, half a drachm twice a day, vitamin B (also A and E) as bemax, half an ounce once a day, and vitamin C in the form of one orange—later increased to two—daily. In addition, of course, he was receiving ordinary diet. This was kept up for over three and a half months (November, 1930, to February, 1931).

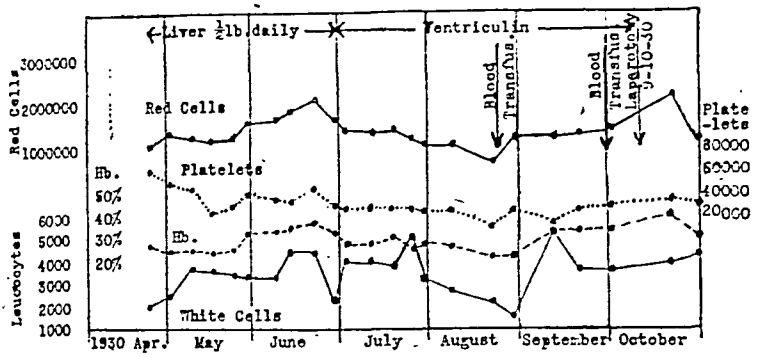

CHART 1.—Showing the changes in the blood occurring while the patient was undergoing treatment with (*a*) liver and (*b*) ventriculin.

The day before the multiple vitamin therapy was begun the blood count was:

Red cells, 1,730,000 per c.mm.; white cells, 3,400 per c.mm.; haemoglobin, 30 per cent.; colour index, 0.9; platelets, 25,000 per c.mm. Red cells well stained, marked variation in size and shape; megalocytes and microcytes; no nucleated reds present, and reticulocytes found only after prolonged search.

Weekly examinations of the blood thereafter showed that from the beginning of the multiple vitamin treatment the red cells, haemoglobin, leucocytes, and platelets steadily increased for the next two to two and a half months. The haemoglobin, leucocytes, and platelets reached their highest limits exactly two months after the treatment had been commenced, and the red cells two weeks later. Blood examination at the end of two months' vitamin treatment showed (January 9th, 1931):

Red cells, 3,500,000 per c.mm.; white cells, 5,400 per c.mm.; haemoglobin, 73 per cent.; colour index, 1.05; platelets, 174,000 per c.mm.; reticulocytes, 0.8 per cent. Red cells well stained and showing variation in size and shape, a few tending to be larger than normal, and others definitely microcytes.

At the end of two and a half months' vitamin treatment the blood showed (January 23rd):

Red cells, 3,840,000 per c.mm.; white cells, 3,200 per c.mm.; haemoglobin, 69 per cent.; colour index, 0.9; platelets, 92,000 per c.mm.; reticulocytes, 0.7 per cent. Red cells well stained, but still marked variation in size; megalocytes and microcytes present.

The progress of the patient was thus far exceedingly satisfactory. At no time since the onset of his illness had he felt so well. The red cells, haemoglobin, and platelets had increased more than ever before, and on only one previous occasion had the leucocytes reached the same level. The reticulocytes, however, were always scanty; once only did they reach 1.8 per cent. Further satisfactory progress, however, was not maintained. The road to recovery had apparently reached its peak, and now began to decline steadily and rapidly. The multiple vitamin therapy was persevered with for another month, but the number of red cells and platelets, and the amount of haemoglobin, rapidly diminished; the blood examination made a few days after stopping the treatment showed that a lower level had been reached than at any previous stage during the administration of liver, ventriculin, or of vitamins. The blood examination was as follows (March 6th):

Red cells, 1,150,000 per c.mm.; white cells, 3,000 per c.mm.; haemoglobin, 27 per cent.; colour index, 1.1; platelets, 21,850 per c.mm.; reticulocytes, 0.8 per cent. Red cells well stained, marked variation in size and shape; megalocytes and microcytes; no nucleated reds.

The patient was now given liver extract (= 1/2 lb. liver) and 30 grams (three tubes in one dose) of ventriculin daily; but he got worse, gradually sank, and, in spite of a blood transfusion (14 oz.), succumbed fourteen days later with a terminal broncho-pneumonia. On the day before death blood examination showed (March 20th):

Red cells, 660,000 per c.mm.; white cells, 1,100 per c.mm.; haemoglobin, 20 per cent.; colour index, 1.5; platelets, 7,800 per c.mm.; reticulocytes, 0.2 per cent. Red cells well stained, varying in size and shape; many megalocytes and a few microcytes present; no nucleated reds seen.

The changes in the blood as they occurred at weekly intervals during the three and a half months when the patient was undergoing multiple vitamin treatment, and up to the date of death, are shown in Chart 2.

COMMENTARY

This case presented the general appearances usually seen in Addisonian pernicious anaemia. It was that of a well-nourished man having a smooth skin with lemon-yellow tint, languid and rather indifferent to the progress of his chronic disease. The blood picture—with megalocytes, microcytes, and poikilocytes, high colour index, leucopenia, and no abnormal white cells—was also characteristic. Erythroblasts were found only once, but the case was not one of aplastic anaemia. The post-mortem examination revealed findings typical of pernicious anaemia; there was a marked hyperplastic, and not aplastic (atrophic), condition of the marrow of the long bones, and a well-marked haemosiderin reaction was obtained in the liver, spleen, and kidneys.

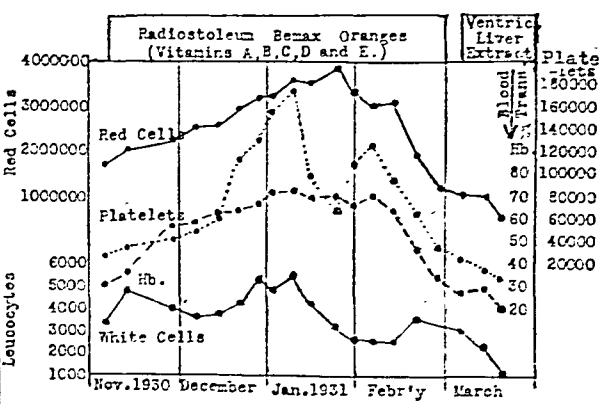

CHART 2.—Showing the changes in the blood occurring while the patient was undergoing treatment with multiple vitamins and, at the end, ventriculin and liver extract.

An unusual feature of the case, however, was the presence of hydrochloric acid in the stomach contents. Fractional test meals were examined about a month after the course of liver treatment was begun in hospital, and also a few days after the beginning of ventriculin treatment. Both showed similar findings. The free HCl

and total acidity followed more or less normal curves. Free HCl went up to about 30 (N/10 NaOH) one and a quarter to one and a half hours after partaking of the meal, and the total acidity to 55. There was no odour in any of the samples, and no blood, bile, or lactic acid ; starch was present up to one and a half hours, and resting juice amounted to 10 c.cm.

Throughout the long courses of treatment with liver, ventriculin, and multiple vitamins, reticulocytes never exceeded 2 per cent., and usually they could be found only after long searching. Under treatment with multiple vitamins the patient, for the first time, showed steady and marked improvement, which reached its maximum degree (3,840,000 red cells per c.mm.) at the end of about two and a half months. At this point, however, in spite of continuation of the treatment, he quickly relapsed, and died a month later with a red cell count of 660,000 per c.mm.

The case, therefore, was resistant to liver therapy and to treatment with desiccated extract of stomach tissue. Although a marked improvement took place under treatment with vitamins A, B, C, D, and E, it was not maintained ; and knowing the tendency of the disease to show periods of natural remission even without treatment, one cannot avoid the conclusion that this may be the explanation, and that vitamin deficiency *per se* is not an essential factor in the causation of the disease. For two weeks before he died he was given both liver extract and ventriculin, but without effect. On three occasions also the other forms of treatment were reinforced by blood transfusion, but the progress of the disease was not influenced thereby.

SUMMARY

(1) A case of Addisonian pernicious anaemia, which resisted treatment by (*a*) liver and (*b*) desiccated extract of stomach tissue, is recorded. (2) Treatment with multiple vitamins (A, B, C, D, and E) was tried, and improvement took place for two and a half months, but was not maintained, and relapse ensued. (3) Liver extract and desiccated extract of stomach tissue were then given, but the relapse progressed and ended in death. (4) Blood transfusions also did not influence the condition. (5) The improvement which took place under multiple vitamin therapy may have been but a natural remission of the disease, and so vitamin deficiency *per se* may not be an essential factor in its causation.

SUBACUTE BACTERIAL ENDOCARDITIS FOLLOWING REMOVAL OF SEPTIC FOCI

BY

LEONARD ABRAHAMSON, M.D., F.R.C.P.I.

PHYSICIAN TO THE RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS ; PROFESSOR OF PHARMACOLOGY, ROYAL COLLEGE OF SURGEONS IN IRELAND

The eradication of septic foci, particularly in connexion with teeth or tonsils, is advocated in all textbooks of medicine. Such advocacy belongs to the realm of elementary teaching, for it is realized that a large number of cardiac patients owe their death to the supervention of subacute bacterial endocarditis, and it is presumed on reasonable grounds that infection in such cases derives from teeth or tonsils. Yet the removal of septic teeth or tonsils in cases of chronic heart disease does not constitute quite so simple a problem as appears on the surface. This is amply demonstrated by the following cases in which subacute endocarditis supervened upon removal of septic foci—teeth (two cases) and tonsils (one case)—in circumstances which leave no doubt that the fatal issue was the result of removal of these foci.

CASE I

A man, aged 39, was seen by me on June 24th, 1925. He had been informed twelve years previously that he had well-compensated mitral regurgitation. From this he had experienced no symptoms whatever. In the middle of January, 1925, he consulted a dentist, who extracted five teeth under local anaesthesia. A week later six more teeth were extracted. Shortly after the extraction he noticed small red spots on his fingers. These were attributed by him to the effects of the cocaine used in the extractions. Soon afterwards he noticed stiffness of his calves and thighs. On April 25th he developed sudden loss of power of his right arm and leg, without loss of consciousness. When I saw him strength had returned to his limbs, but a number of petechiae were noted on his fingers. These were, he stated, similar to the earlier spots. His temperature showed an evening rise varying from 99.4° to 101°, while his pulse rate varied from 90 to 120. Examination showed the presence of mitral regurgitation, without enlargement of the heart. Blood culture yielded a growth of *Streptococcus viridans*.

The next event in the case was the appearance of tender nodules on a finger, on the right arm, and on the right buttock. Crops of petechiae appeared from time to time in various parts. On July 25th sudden pain was felt in the right shoulder. This lasted for two days, and was followed by a shower of petechiae in the region of the right clavicle and scapula. More tender nodules were observed on the left wrist, left leg, and buttock. On September 20th, 1929, intense pain was experienced in the back of the head. This was followed by unconsciousness and, in a few hours, by death.

CASE II

A male, aged 21, had a history of rheumatic fever in childhood. A year after this infection he was able to indulge in vigorous exercise without discomfort. After a time he hunted, and rode in point-to-point races with considerable success. In July, 1929, he obtained his degree, but failed to pass the medical examination for the British Army. Until this time he was quite unconscious of the presence of any defect in his heart. The result of his medical examination caused him considerable surprise, and he thereupon consulted a London cardiologist, who found a valvular lesion, and advised removal of tonsils, which were, he found, in a septic condition. The tonsillectomy was followed by pyrexia, and ten days later the patient returned to Ireland. On the evening after his return he had a violent pain in his right hip, and was then seen by Dr. Drennan, who has kindly permitted me to publish this case. Examination revealed a good deal of sepsis in the throat, swelling and tenderness of the right hip, a temperature of 103°, and a pulse rate of 120. An aortic diastolic murmur was heard.

After some days the throat condition improved and the swelling of the right hip subsided. The temperature came down, but failed to reach the normal, and for some weeks there was an evening rise towards 100°. Pain and swelling attacked a number of joints, and with this a progressive anaemia became apparent. Six weeks after his return to Ireland I was called to see the patient. The throat was still septic, the temperature was 102°, and the pulse rate 120. The patient looked extremely pale, almost ashen ; a few petechial spots were seen on the legs, and there was considerable sweating. The heart showed moderate enlargement, with aortic and mitral regurgitation. Blood culture yielded a pure growth of *Streptococcus viridans*. The course of the infection after this date followed the lines previously exhibited. Remissions occurred in which the general condition improved and the temperature fell, though never reaching normal. After each remission an exacerbation was ushered in by joint-pains, weakness, increased pyrexia, and sweating. Cardiac enlargement became more marked, and anaemia more profound. After seven months death ensued from cerebral embolism.

CASE III

Male, aged 53, suffered from a sudden attack of auricular fibrillation in September, 1927. He came under the care of Professor T. G. Moorhead, who has kindly permitted me to record his case. During a period of eighteen months after his initial attack of irregularity, repeated attacks occurred of paroxysmal fibrillation with some flutter. The heart showed moderate enlargement, with a systolic murmur maximal in the mitral area. Complete examination failed to show any cause for the irregularity. His teeth were carefully examined by a dentist in November, 1928, and were pronounced sound. Early in 1929 the patient began to suffer from some discomfort with his teeth, and a general deterioration of health was noted, as evidenced by considerable loss of weight, with increasingly frequent incidence of fibrillation. In April, 1929, he consulted a London cardiologist. His teeth were *x*-rayed and two roots were condemned. Removal of all his teeth under local anaesthesia was recommended. In May, after an abortive attempt to improve the condition of pyorrhoea which then existed, two teeth were removed without difficulty, the only anaesthetic employed being cocaine, which was simply painted on the gums. On June 27th another tooth was removed. This extraction proved difficult, and some novocain was injected into the gums. Following the extraction the gums continued to bleed for three days. The bleeding ceased after application of adrenaline. On July 1st a purpuric eruption occurred all over the body. On the next day there was pronounced haematuria, and oozing of blood was noted all over the surface of the palate and from the gums. Haemostatic serum and antistreptococcal serum were administered and the bleeding ceased. Four days later there was haemorrhage from the stomach and bowel, and, from this on, the patient was mildly pyrexial. Blood culture was negative. At this time I saw the patient in consultation on two occasions. No marked change was noted until August 14th, when he was apparently much better and able to go for a drive. On the next day he was not so well, and was again feverish. Haematuria once again appeared, and there were more purpuric spots. Two days later it was noticed that the left arm was paralysed. Half an hour later the left leg was paralysed, and still later the left side of the face. Towards evening there was severe haematemesis, after which the patient sank into coma and died.

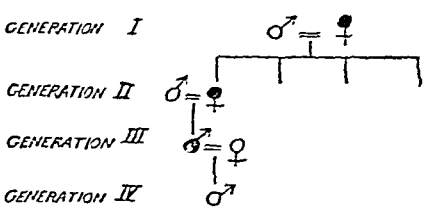
COMMENTARY

It will be seen that in two of the cases recorded above there was no symptom or sign of endocarditis until the removal of septic foci. The first patient had experienced no disability whatever from his heart lesion, and consulted a dentist because of trouble with his teeth. The second patient was led to consult a cardiologist because of rejection for the Army. His valve lesion had not interfered with indulgence in strenuous exercise. The third patient had presented a number of symptoms before the removal of teeth, but the terminal illness was closely associated with an extraction. I feel justified in including his case in this paper in spite of negative blood culture, as the circumstances associated with his death point the same moral as the other cases.

Many interesting problems arise from consideration of these cases. If proof were needed that infection in subacute endocarditis may derive from teeth or tonsils, such cases would supply the necessary evidence. Paradoxically, then, they emphasize the importance of removal of septic foci, but they stress the need for great caution. Removal of more than one or two teeth at a sitting in patients with disease of the heart is clearly unwise. Unless there is a definite periapical abscess it would seem equally unwise to risk dissemination of infection by removing teeth which are very firmly fixed and require much manipulation. General anaesthesia should on *a priori* grounds be preferred to the use of local anaesthesia. Preliminary vaccination with an autogenous growth from the gums or tonsils seems a rational procedure. Careful supervision of teeth in patients with disease of the heart should obviate the necessity for wholesale extractions. Crowning of teeth in such patients and the preservation of dead teeth are both to be condemned. It is better to sacrifice a comparatively useful tooth at a stage when its removal is unattended with danger, than to preserve it in a condition in which it is likely to become severely infected and a source of danger whether it be left or removed.

THREE GENERATIONS OF INHERITED DENTAL DEFECT

BY



MARGARET E. RUTHERFURD, M.B., CH.B.

MANCHESTER

Congenital absence of certain teeth is a relatively common condition which sometimes occurs in family groups, but gross suppression of the majority of the teeth in members of three consecutive generations of the same family is rare.

Recently a woman attended an infant welfare centre with her only grandson, a boy 8 months old, who had six teeth already erupted. Mention of these teeth led the woman to volunteer the statement that her own two widely spaced teeth were the only ones she ever possessed. These peg-shaped teeth, occupying the place of the lower central incisors, appeared when she was about the age of 7, and are still strong and sound, being implanted in firm gums, which, she says, have always been capable of dealing unaided with all kinds of food except nuts. During childhood, complete closure of the mouth was impossible owing to hypertrophy of the gums, but it was not until she reached the age of 19 that, goaded by her companions' constant teasing on account of her toothlessness, she sought advice at the local hospital. Two "levelling" operations ("for double odontoma," she says) took place, after which the gums shrank to their present normal proportions, and she was able to close her mouth naturally.

Her memory regarding the results of *x*-ray examination then and later is vague; but apparently when she was 19 a few rudimentary teeth were said to be present, and again, twenty-seven years later, when she was in another hospital for gynaecological treatment "almost a full set of teeth" was found. Operation on the mouth was then suggested, but she would not agree to this as her bite was satisfactory, and her enunciation clear and unusually

good. She is one of a family of four, all the others having normal dentition. Her age is 46, but her appearance is that of one twenty years or so older. She is stout and florid, and her abundant dark hair is going grey. "A complication of disorders"—the graphic phrase of some former biographers—might sum up her past and present health, for she has never been strong, having suffered from "chronic bronchitis, gall-stones, appendicitis, and displaced kidney," and having had, eight years ago, after several curettages, a major gynaecological operation, of the nature of which she is unaware.

THE FIRST GENERATION

The mother (Generation I) of the above patient, who died at an advanced age, was one of a family of eleven children, and was "the only one with bad sight or anything the matter with her teeth." She had "no teeth until she was grown up, and then two came right under her tongue." She was short-sighted, a good speaker, and photographs show the usual edentulous sinking-in of the lower part of the face such as occurs after multiple extractions or in old age. History farther back is unobtainable, except that the family, on each side, has been country-born and bred for many generations, and has always been used to an ample diet containing fresh milk and vegetables. Despite this woman's appearance, no Semitic element is known on either side of the family, and the living members now under consideration are of good intelligence and physique.

THE THIRD GENERATION

The third generation consists of the only grandson of the old couple, a young man, father of the infant first mentioned. At the age of 15 he had no erupted teeth, but now, at the age of 23 years, he is teething, and has at the present date two more teeth than has his 10-months-old son. His gums are still enormously broad, but evidently are much reduced following an operation done when he was 15. At that time localized pain and inflammation round the ? second upper right molar induced him to go to the dental hospital, where a local abscess was evacuated. *X*-ray examination, when he was 9, and in a children's hospital, "as he was not very strong," is said to have shown "few teeth in the jaws, and these only stumps," but six years later a full set of unerupted teeth was found to be *in situ*. Soon after this he was referred to a general hospital, where, after another *x*-ray examination which corroborated the above, he says both gum and bone were "chiselled off" and four teeth set free. Reference to an early photograph shows the inability to close the mouth prior to the operation, as happened in his mother's case; no such disability was present afterwards.

The right upper molar referred to juts out on the outer aspect of the maxilla at an angle of 35 degrees or so, and around it inflammation occurs occasionally, but to a less extent than before. The visible teeth are odd and asymmetrical in shape, though not at all Hutchinsonian; they are very broad proportionately, probably because they are only partly erupted, though strong and fairly firmly set. As far as their oddity allows descriptive enumeration, all the incisors seem to have erupted except the left upper one; the right and left lower canines are present, as is the left upper one. Behind the canines the gum in the lower jaw is less thick than in the upper jaw. The patient's enunciation and bite are now excellent, and he is an expert whistler.

A COMMON EYE DEFECT

Common to this family there is an eye defect to which, curiously, they have given little attention or treatment. The baby's grandmother has always had extremely defective sight, and has been almost blind for the last four or five years, dense bilateral corneal opacity being now present. She says she "brought this into the world with her," and apart from some treatment at the age of 9 or 10 years, its course has been unchecked. A year ago she was prevailed on to attend hospital, and was then told the damage was irreparable. She is active and handy in her house, though she leaves machining and hand-sewing to her son; she peers—though she can see neither the printed page nor a human face—closely at all she handles, declaring herself benefited by the use of strong concave glasses purchased from a hawker for a relative now deceased. Her own mother, possessor of the "two teeth under her tongue," had, she says, "exactly the same kind of eyes as mine," with very defective, untreated sight; and her father, a venerable old man by his photographs, always had poor sight, and went blind when he was 47. Both these old people had abundant hair. Her son, father of the baby in Generation IV, has a slight degree of bilateral keratitis with defective sight, for which he wears glasses, "fours or fives," obtained "from a young gentleman at the door" (who supplied the other glasses mentioned). He has neither had, nor desired, any other form of treatment. The infant, whose head and face show extreme asymmetry from whatever aspect they are regarded, has an alternating squint. He is well grown, but some developmental genital defect is also present, for neither testicle is descended, and the scrotum is absent, or almost so. He plays happily in his cot, and is already quickly responsive to the sound of a piano or band, but he is considered by his grandmother to be "not at all well," owing to teething.

COMMENTARY

The available bibliography illustrates the heritability of similar dental defects, either fixed from one generation to another, or variable; and also an association with certain epiblastic defects, not present in the family under consideration. This family differs also from Thurnam's case (*London Med. Chir. Soc. Trans.*, 1848, p. 71) of two cousins, each of whom had only four teeth and was the subject of congenital alopecia, the scalp hair being represented by lanugo only. He also quoted additional cases. Danz, according to Michelson (Ziemssen's *Handbook*), saw two adults who had never had either hair or teeth. Another condition of congenital absence of cutaneous appendages is known in which teeth, hair, and sweat glands are all either rudimentary or suppressed. Such subjects, with their undeveloped alveolar processes and normal development of the upper part of the face and head, suggest in their features a curious resemblance to a foetal skull, and are apt to become severely distressed in hot weather owing to heat retention, and inability to reduce their body temperature by sweating. A small family group of two persons who appear to correspond to the above type has been recorded by Dr. Jean Smith, in two successive communications in the *Proceedings* of the Royal Society of Medicine (1929, xxii, 649; January, 1931, xxiv, 323); two brothers showing this dental defect, along with absence of sweating and a tendency to attacks of pyrexia (apparently from insufficient heat loss in absence of sweating), and scanty hair. The special value of her records lies in the *x*-ray picture accompanying the second record, to which reference may advantageously be made. She alludes to Clouston's account in the *Journal of the Canadian Medical Association* (1929, xxi, 18) of a French-Canadian family in or near Quebec in which 119 of such cases are said to have occurred throughout six generations. Apart from this family group she states that she had only succeeded in tracing the record of fifteen similar cases in the literature. Thadani, however, reports (*Journ. Hered.*, 1921, xii, 87) a Hindu Amil community in India, in which a toothless type of man occurs. The men are not only toothless, but bald-headed and extremely sensitive to heat. The evidence, as far as it goes, indicates that the character is male sex-linked. Anodont females are not at present known, but if daughters of a toothless father are married to a normal man their male children are toothless, and they seem to be known locally as bhudas, or old men. Crosman (*Journ. Hered.*, 1927, xviii, 368) cites from Guildford in 1883 a not dissimilar type of case, in that of an edentulous woman without teeth or hair. She had a son in the same condition.

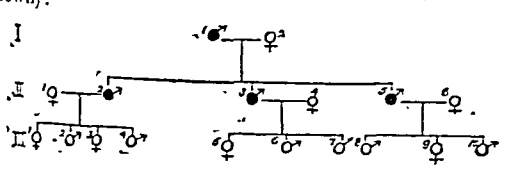
He married a normal, and of their children six were normal and two others had several undeveloped teeth. A normal sister had eighteen children, one of whom was without teeth or hair. Fürst (*Arch. f. Rass.- u. Gesells.-biol.*, 1905, xvi, 310) describes another case of anodontia.

Any possible connexion of rickets in the etiology of this condition need not be considered here, as a hereditary genetic defect displayed in three successive generations cannot possibly be due to such or to any other form of malnutrition or vitamin deficiency.

From all the foregoing cases this family group is essentially different, in that the primordia of the teeth are not suppressed, being present in the gums even when dentition is either greatly delayed or never completed. Sweating is normal here, and the hair is as abundant in all the affected members as it is in ordinary members of the general community. It is just conceivable that as the teeth are epiblastic appendages, and the corneal epithelium and the lens itself are also epiblastic in origin, the eye defect in this family and its inherited dental condition may be associated characters, joined or linked together in the process of heredity. Whether this is so or not must at present be left an open question, though the association itself is certainly suggestive.

I have to thank Dr. Veitch Clark, the medical officer of health, and Dr. Maude Duckworth, at whose infant welfare centre under the Manchester Corporation the infant was seen, for permission to publish notes of the above case; and to acknowledge to R. R. Gates's *Heredity in Man* (1929) my indebtedness for references to the literature.

HEREDITY AND DUPUYTREN'S CONTRACTION



BY

J. S. MANSON, M.D., D.P.H.

FORMERLY ASSISTANT SURGEON TO THE WARRINGTON INFIRMARY

The hardening and contraction of the palmar fascia, resulting in flexor contraction of the fingers named after Dupuytren, has been known for many years to have had a hereditary factor in its etiology. This factor has been thought usually to be of a gouty nature, influenced by occupation. It is rare to come across three brothers affected with the deformity, whose father was also affected, and whose mother was affected by double-bent little finger at the proximal interphalangeal joint, but whose other fingers were normal.

The father died at the age of 73, and the mother at the age of 63. All the affected followed different occupations. The father was a grocer, and the brothers were a baker, clerk, and general labourer, their present ages being 72, 70, and 68 respectively. There is no history of gout in the family. The pedigree is as follows (a female infant in Generation II, who died in infancy, is not shown):

Description of Members of Pedigree

I 1: Both hands affected; third and fourth fingers contracted; began at about the age of 50.

I 2: Both little fingers (fourth) bent at proximal interphalangeal joint; said to be from birth. Other fingers unaffected.

II 1, 4, 6: Unaffected.

II 2: Both hands affected; right first and fourth fingers, noticed first at the age of 57; left first, second, third, and fourth, noticed first at the age of 37, after receiving injury to second finger.

II 3: Both hands affected; noticed first about the age of 40. Right first, second, and third fingers; left second and third fingers. Both fourth or little fingers are bent at the interphalangeal joints similar to his mother's.

II 5: Both hands affected; began at the age of 48. Right third and fourth fingers; left second, third, and fourth fingers.

III 6: Died in infancy.

III 7: Died, aged 23, unaffected.

III 1, 2, 3, 4, 5, 8, 9, 10: All unaffected—ages from 41 to 33.

It will be observed that there is some slight variation in the degree of deformity. II 2 and II 5 have the greatest deformity in the left hand, while in II 3 it is the right hand which is most affected. In all three the fourth or little finger is affected, and it is difficult to decide whether the maternal character as well as the paternal is shown, or whether the maternal factor has reinforced the paternal factor so as to produce the very marked deformity in all three brothers.

So far the deformity has not appeared in the third generation, but this generation has hardly yet reached the age when it begins to be noticed. The late period in life—advanced maturity—when the deformity appears and continues to progress, illustrates the potency of the hereditary factor which lies dormant during childhood, adolescence, and maturity.

There may be other defects or diseases appearing late in life which have a hereditary basis, but are not so easily recognizable clinically as Dupuytren's contraction. Owing to the difficulty of disentangling and analysing the various factors these defects or diseases are attributed chiefly to environmental causes.

Senescent hereditary defects or diseases are more difficult to study with the completeness of those occurring in earlier years, because many members of families do not live long enough for the defect to appear, and develop to such a degree as to be recognizable.

DISSEMINATED ENCEPHALO-MYELITIS FOLLOWING SPINAL ANAESTHESIA

BY

T. KAY MACLACHLAN, M.A., M.B.CAMB., F.R.F.P.S.GLAS.

HONORARY CONSULTING NEUROLOGIST TO THE EYE INFIRMARY; ASSISTANT PHYSICIAN TO THE ROYAL INFIRMARY, GLASGOW

Although spinal anaesthesia was introduced by Bier of Bonn in 1889 the method has been generally employed only since the discovery of stovaine in 1904. Toxic effects at the time when stovaine was on trial, and its known action in lowering the blood pressure and depressing the cardio-vascular and respiratory systems, discouraged many surgeons for a time from the employment of spinal anaesthesia. For many years it has been successfully used by those aware of its dangers and of the technique of administration; and in a large field of surgery it now appears to be the anaesthetic of choice. Those who employ this method have recorded series of thousands of cases without any immediate ill effects or sequelae, and the majority of deaths which have occurred under spinal anaesthesia have been due to the state of the patient prior to operation, shock, cardiac disease, and to loss of blood, etc.—conditions which would make the operation more hazardous if performed under chloroform or ether.

Headache, paraesthesiae, and even pain in the trunk and limbs, not uncommonly follow spinal anaesthesia. More rarely paralysis of an ocular muscle occurs, but recovery is usually complete within a few weeks. More

serious affections of the nervous system are very rare; but there are records in the literature of such varied neurological sequelae that I would submit the description of two cases where the onset of symptoms appeared to be too closely related to spinal anaesthesia to be entirely unconnected with its administration.

CASE I

Mrs. N. W., a healthy woman aged 38, had a hysterectomy performed for fibroids in August, 1929; the tissue was subsequently examined histologically, and there was no evidence of malignancy. Spinal anaesthesia with stovaine was employed.

Four days after the operation, from which she otherwise made an uneventful recovery, she noticed that her right arm was useless and weak, so that she had difficulty in feeding herself.; within the next few days she complained of weakness in both legs and some dimness of vision. These symptoms became more marked, and finally all the limbs were completely paralysed and flaccid. The onset of the complete paralysis was associated with headache and delirium, which persisted for about a fortnight; she had diplopia and such deficient vision that she was unable to recognize those in the room. There was retention of urine and faeces. Improvement was gradual over a period of months. She recovered the use of the left arm, and although the right remained very weak, some degree of movement was possible at all joints. Vision was restored to such a degree that she was just able to read large print; and although her right arm showed ataxic movements at the onset of her illness, both inco-ordination and tremor passed away. Both lower limbs remained completely paralysed, but without sensory loss, although paraesthesiae, burning, and a feeling of weight were present in each. The pupils were equal, central, and circular, and reacted both to light and on convergence; the arm-jerks were present and not exaggerated; the abdominal reflexes were absent on the right side and very sluggish on the left. There was no spasticity of the lower limbs, but both knee jerks were exaggerated; the ankle-jerks were present and equal, and the plantar responses were flexor. Speech was little impaired, while intelligence was unaffected; no emotional disturbance persisted. There was no diplopia, but nystagmoid movements were noted in the horizontal plane. Retention of urine and faeces has persisted since the onset of the cerebral symptoms and the general paralysis.

The above represents the clinical picture when she was seen by me with Dr. Alexander of Darvel nine months after her operation, and Dr. Alexander informs me that now, some twenty months after the onset of her symptoms, very little further improvement has taken place. She is bed-ridden, with almost complete paralysis of both lower limbs; the right arm is still weak; sphincter control has in a small measure been regained. Before the operation she had enjoyed excellent health, was the mother of two healthy children, showed no evidence of syphilis, clinically or serologically, and had never previously experienced even transient nervous symptoms. As in the other patient, there is no history of any familial disease.

CASE II

G. Y., aged 35, had an operation for left inguinal hernia under spinal anaesthesia with stovaine in August, 1929. The wound healed by first intention, and the recovery from a surgical point of view was uneventful.

During the first few days following the operation a change in his speech was noted in that it became thick and deliberate, with occasional mispronunciation of words; and at the same time the left hand became clumsy, so that he was unable to fasten buttons and carry out fine movements, though there was no objective paralysis. There was no sensory loss, but the arm and leg felt numb; and, though there was delay in commencing micturition, catheterization was never required. He had slight transitory dimness of vision, but no ophthalmoscopic changes were detected. Later the left leg became weak and stiff, and he dragged it when walking, and with this stiffness there was associated a feeling of heat in the whole limb.

When seen by me six months later he appeared a well-built man with healthy organs. There was no evidence of arterial degeneration, and the blood pressure was within normal limits. Both legs were weak, especially the left, and when walking the latter limb was stiff and dragged slightly. The deep reflexes were exaggerated in both limbs, especially the left; ankle and patellar clonus were elicited, and on the left side the plantar response was indefinitely extensor. There was no intention tremor, diplopia, nystagmus, or emotional disturbance, but though Romberg's test was negative he had some difficulty in walking heel-to-toe. There was no sensory loss and no astereognosis.

The left arm showed more weakness than could be accounted for by the fact that he was a right-handed man, and he was definitely clumsy in carrying out fine movements with this hand. There was no obvious muscular atrophy. The abdominal reflexes were very sluggish on the right side and absent on the left.

Lumbar puncture gave a clear fluid under increased pressure; protein was increased; sugar was normal; no organisms were seen; and there was only one cell per c.mm. The Wassermann reaction was negative in the fluid and also in the blood, while the colloidal gold curve was 0022110000. He has since made slow but continuous improvement.

The only sequel of spinal anaesthesia, apart from headache and paraesthesiae, which I had previously seen was diplopia from paralysis of an ocular muscle; but meningomyelitis after anaesthesia has been described by Donovan, Beretervide, and Richniewski,[1] and a degenerative myelitis has been recorded by Nonne and Demure.[2] Trophoneurotic disturbances have also been observed; and Devraigne, Suzor, and Laennec[3] had a case where quadriplegia followed anaesthesia. Post-anaesthetic confusional insanity, epileptiform seizures, double optic atrophy, and vitiligo have all been recorded as sequels of spinal anaesthesia.

Considered from the point of view of the nervous systems alone, both cases which I have described could be diagnosed as disseminated sclerosis; and even with their post-operative onset, I am aware that many would still consign them to that dumping-ground of neurological diagnosis. But from the onset of the symptoms so soon after spinal anaesthesia, which we know can be occasionally followed by the most varied nervous symptoms, I consider that their relationship to the anaesthesia is more than merely fortuitous.

HYOSCINE AMNESIA IN LABOUR, WITH OR WITHOUT CHLOROFORM

A RECORD OF THIRTY-FIVE CASES

BY

ANDREW M. CLAYE, M.D., F.R.C.S.

HONORARY OBSTETRIC SURGEON, LEEDS MATERNITY HOSPITAL; HONORARY ASSISTANT SURGEON, HOSPITAL FOR WOMEN AT LEEDS

I started using this treatment as a result of reading the article on hyoscine amnesia in labour by Dr. D. R. Jennings in the *British Medical Journal* of November 2nd, 1929. The cases were not selected, except that no patient who was suffering or had suffered from albuminuria was treated.

Van Hoosen's dosage, as quoted by Jennings, was employed, with only slight modification in a few cases—that is, three doses of 1/100 grain of hyoscine hydrobromide hypodermically at half-hourly intervals, and thereafter 1/100 grain every two hours as long as labour lasts.

In twenty-one of the cases chloroform was also given in the second stage. This is the present practice of the Leeds Maternity Hospital, and I think that where birth occurs about the time when the third injection is due it

may ensure a case being a complete instead of only a partial success.

ANALYSIS OF CASES

Of the 35 patients, 24 were primiparae and 11 multiparae, their ages varying between 18 and 40 years. There was one poorly flexed occipito-posterior position, which called for manual rotation and forceps ; 6 other patients had low forceps deliveries ; 27 cases were normal ; 1 was not in labour. The incidence of forceps deliveries is high, but the series is not large enough to generalize on this point. In one case the indication was contracted pelvis.

RESULTS

Five patients had fewer than three injections, and had little or no amnesia ; in these cases the treatment was started too late to be effective. One patient had five injections before it was realized that she was not in labour. Of the remaining 29 cases, 19 are classified as excellent results, 3 as good, 3 as doubtful, and 4 as unsatisfactory.

Four Unsatisfactory Cases

In the first two of these the treatment was faultily carried out.

Case 12.—1-para, aged 28. Six injections. After the sixth dose, was seen by a doctor who was unfamiliar with the low delirium commonly present in these cases, became alarmed at it, and stopped the treatment. The baby was born six hours fifty-five minutes after the last dose, and the patient consequently remembered all the last part of the labour.

Case 21.—1-para, aged 23. Five injections. Time from first injection to delivery, eight hours fifteen minutes. Sixth injection was due one hour before delivery, and was forgotten. She remembered some of the later stages and the administration of chloroform, which was given at the end of the second stage.

Case 25.—1-para, aged 34. Four injections. Time from first injection to delivery, three hours ten minutes. Comatose after second injection to the end. No chloroform. Remembered the terminal pains.

Case 30.—1-para, aged 25. Eight injections. A case of primary inertia. Treatment stopped after eleven hours, very little advance having been made in spite of thymophysin 1/2 c.cm. The baby was not born until twenty-four hours forty-five minutes after the last dose.

Three Doubtful Cases

Case 4.—5-para, aged 31. Three injections. Time from first injection to delivery, two hours. No chloroform. Soon after delivery would not believe that the baby was born. Remembered three injections. Later she said she remembered one pain at the birth. Very much pleased with the treatment.

Case 20.—6-para, aged 33. Two injections. Time from first injection to delivery, 55 minutes. No chloroform. Treatment begun too late. One hour after delivery remembered the birth, but one and a half hours later had forgotten it.

Case 24.—8-para, aged 30. Three injections. Time from first injection to delivery, one hour thirty minutes. Terminal chloroform. At first said she remembered the final pain, but later was surprised to hear that the baby was born.

Three Good Cases

These patients had very fair amnesia, and were pleased with the treatment, but there was a memory island in each case ; they cannot therefore be classified with the " excellent " results.

Nineteen Excellent Cases

By " excellent " I mean that after one (two cases), or two (fourteen cases), or three (three cases) injections the patient had no recollection whatever of subsequent pains. The only satisfactory judge of the results of this treatment as far as the amnesia is concerned is the patient, and any case not coming under the above definition is omitted from the " excellent " list. It is necessary to have a high standard. Case 25 cited was in coma for the last two and a half hours of labour, but said she remembered the last pains, and so is labelled unsatisfactory. A typical comment from one of the " excellent " cases, a 2-para who had had a previous unrelieved labour, was: " I never felt any pain at all: it was wonderful." The number of injections received by the " excellent " cases was as follows:

3 (10 cases).
4 (3 cases).
5 (1 case).
6 (3 cases).
7 (1 case).
8, one being only 1/200 grain (1 case).

Of these patients, six received terminal chloroform, according to the present practice of the hospital ; seven were anaesthetized for forceps application.

It is interesting to note that in one of the nineteen (Case 22, a 1-para, aged 24) treatment was stopped after the third injection, owing to her extreme violence ; the baby was born three and a quarter hours later. In spite of this amnesia was perfect.

Thirty of the patients were confined in the Leeds Maternity Hospital, and five in private houses or nursing homes.

THE BABIES

Our experience corresponded with that of Jennings. All the babies were born alive, and all breathed and cried at once, and gave no subsequent trouble while under our care, except three.

Case 1.—This baby was born with a caul, and was consequently cyanosed. Its colour became pink within a few minutes after clearance of the air passages and a warm bath ; subsequent progress was normal. The cyanosis cannot be attributed to hyoscine (three injections).

Case 3.—The baby breathed normally at birth, but both mother and baby were drowsy for several days. The baby required a good deal of coaxing when feeding during this period. This condition may have been due to hyoscine. Both were normal before discharge from hospital (three injections).

Case 4.—The baby had a hare-lip. It was cyanosed at birth, but was quite normal as regards colour, breathing, and crying twenty minutes later, having been immersed in a warm bath.

Much exaggerated adverse comment has been made on the condition of the babies after twilight sleep. Even with the older morphine-hyoscine treatment I have never seen a stillbirth occur without some adequate reason for it apart from the drugs, and when hyoscine is used alone even the occasional oligopnoea (a condition of no serious moment) seen with morphine-hyoscine is not encountered. When one also bears in mind that asphyxia and stillbirth are by no means unknown in normal deliveries, apart from the use of drugs, it is quite unjustifiable to say, when a patient asks for twilight sleep, that it harms the baby.

CONDUCT OF THE CASE AND APPEARANCE OF THE PATIENT

I agree with Jennings that treatment should not be started before regular pains are present. As a rule I have not given the first injection in a primipara before the cervix is three fingers dilated.

I have not come to any conclusion about the maximum safe dose. The highest dose given in this series was 8/100 grain, without ill effect. Greenwood[1] gives details of a case in which he used 1/10 grain safely, with morphine.

I agree also that most patients remember receiving the first two injections. Whether the treatment accelerates labour I am doubtful. The time of the onset of labour and the time of the beginning of the second stage are points which it is almost impossible to determine accurately. However, Case 30, the patient with primary inertia already quoted, was the only one in which labour was not completed within thirteen hours of the first injection. I am therefore reasonably satisfied that hyoscine does not delay labour to any appreciable degree.

A doctor, or a nurse who is familiar with the treatment, should stay with the patient all the time. External stimuli should be excluded as far as possible. If there is a light it should be kept shaded except when urgently required. The attendants must be absolutely quiet, and refrain from disturbing the patient beyond what is necessary. I have not used the memory test on this account. The effect of the injections usually becomes obvious after the second. The patient begins to sleep between pains; she usually lies quiet. When a pain comes she shows that she feels it, and tosses about. She mutters like a delirious person, but as soon as the pain goes she stops, maybe in the middle of a sentence, and falls asleep at once. Some patients become very restless, or attempt to get out of bed. A few lie comatose even during the pains. Coma, great violence, or a slowing down of the pains are indications for prolonging the interval between injections. Undue wakefulness calls for a shortening of the interval. The pupils soon become dilated. In most of our cases the pulse rate rose, in some to over 120. Often it fell again as labour proceeded, and always within a few hours of the birth. The rise may be explained by the restlessness or by the effect on the vagus. The bladder should be carefully watched. The patient soon becomes thirsty, and asks for a drink, especially in the first few hours; this should be given. Some patients cannot see well owing to paralysis of accommodation for twenty-four hours or so after the birth. It is important not to omit the last injection, even if the child is about to be born; otherwise the worst pains may be remembered, and the whole labour reconstructed by the patient from them. Additional help, as Jennings says, may be required at the time of delivery. The "obstetric helper" is a useful appliance for keeping the patient in position in the later stages. Our experience did not bear out Jennings's observations on the expulsive pains. These were as a rule remarkably strong, and the abdominal muscles certainly played their part.

With practice it should be possible to obtain a much higher percentage of complete successes than has been obtained in this series, and I have no doubt I shall do so. I have dwelt on the less satisfactory cases because, as experience, they are more valuable than those that are perfect. I hope that others will be encouraged to use the treatment; the success, demonstrated by the patient's gratitude, is a great reward for the trouble involved.

I offer my thanks to the other members of the honorary staff of the Leeds Maternity Hospital for permission to use the treatment on their patients; to Mr. A. J. C. Latchmore, who performed most of the forceps deliveries, and was of great assistance in the management of the cases; and to those students of the Leeds School of Medicine who gave their help in compiling the records on which this paper is based.

PHIMOSIS AND CIRCUMCISION

BY

A. ERNEST SAWDAY, M.B., B.S.LOND., F.R.C.S.ED.

LATE HONORARY SURGEON TO THE DERBYSHIRE HOSPITAL FOR SICK CHILDREN

Circumcision is an operation performed with great frequency. It is obviously bad surgery to perform any operation without definite indications, and probably no operation, with the possible exception of tonsillectomy, is frequently advised upon more slender grounds than that of circumcision.

The term phimosis implies such a narrowing of the preputial orifice that the foreskin cannot be retracted over the glans. A foreskin which can be easily and completely retracted without effort is very rare indeed. Phimosis may be of several degrees:

1. A pin-hole preputial orifice smaller than the urethral orifice. This is the only degree in which obstruction to the urinary stream is possible. Apart from cicatricial contraction resulting from inflammation (vide infra) it is very doubtful whether phimosis ever produces urinary obstruction. It is reasonable to suppose that healthy and distensible skin will allow the rapid dilatation of the orifice by the ordinary stream to the required size.
2. A match-head orifice.
3. A wide preputial orifice with adherent prepuce (crowned glans).
4. Coronal adhesions.

Any of the above conditions may be associated with a long, lax prepuce.

Popular indications for circumcision include restlessness, straining during micturition, and enuresis. Congenital stenosis of the terminal urethra is a condition which should be borne in mind, for in such a case it is of course futile to attend to the phimosis and overlook the urethra. If circumcision has any effect on enuresis it is probably a psychical effect, which would equally result from any operation.

DILATATION AND RETRACTION OF THE PREPUCE

This procedure is safely carried out and is eminently satisfactory in infants. In older children it may be unsatisfactory owing to the undesirability of carrying out manipulations over any period of time.

Technique.—The only instruments required are a fine probe and a pair of Spencer Wells artery forceps (not too blunt). The first step is the complete separation of the prepuce from the glans. The prepuce is grasped between the thumb and fingers of the left hand and retracted as far as possible. The probe is then inserted (care being taken not to enter the urethra) and swept right round the glans. This manipulation also serves to stretch the preputial orifice slightly. If the prepuce cannot now be retracted, the point of the artery forceps is inserted into the orifice and pushed up as far as it will go between the prepuce and the glans. The blades are then gently separated for a few seconds. It will now be possible to retract the prepuce, exposing the urethra and part of the glans. If complete retraction is not possible the artery forceps are inserted again, care being taken not to split the prepuce. In very resistant cases it is well not to attempt complete retraction at one sitting, but to leave it for a week. When the foreskin has been completely retracted the smegma in the trough round the corona is wiped out, the glans smeared with sterile olive oil and the prepuce drawn down. The preliminary separation of the prepuce from the glans is important, as otherwise the point of the forceps will be found merely to carry the orifice inwards without penetrating it. The mother is instructed to retract the foreskin daily as far as possible, *but not to leave it back.* Nevertheless in a few cases paraphimosis will occur. This, as a matter of fact, may serve a very useful purpose if it is not neglected too long. One often finds after paraphimosis that the foreskin is quite lax and retracts easily. The child is seen every week for a few weeks. The foreskin is retracted, and the glans, having been smeared with olive oil, is brought down again. In two or three weeks' time it will be found to retract very easily. As soon as there is no danger of a paraphimosis it can be left back altogether.

INDICATIONS FOR CIRCUMCISION

The indications for performing circumcision may be grouped as follows:

1. Cases that come from a distance and cannot attend regularly, unless the prepuce can be very easily retracted and is unlikely to cause further trouble.
2. Some boys over 12 months old.

3. Most patients over 3 years—always excepting those cases of "crowned glans" or cases with only marginal adhesions round the corona.
4. Recurrent dermatitis and fibrous thickening round the preputial orifice.
5. Balanitis if persistent. One sometimes sees cases of purulent balanitis put down for circumcision and when the child is sent for some months later the condition has completely cleared up.
6. Repeated paraphimosis.
7. A few cases of unsuccessful stretching. These cases are very rare in infancy, and are almost invariably due to lack of interest on the part of the mother.

Hypospadias is an absolute contraindication. All the available skin may be required for an operation of the Mayo or Russell-Duplay type.

The question naturally arises, "Why, in the absence of actual obstruction to the urinary flow, should the infant's prepuce be interfered with at all?" The adhesions between foreskin and glans which are so common in infancy do certainly tend to disappear as the child gets older, and the foreskin may retract perfectly easily. This is the ideal to which nature does not always attain. A permanently retracted foreskin or a foreskinless organ is more hygienic than an organ in which the glans is more or less covered up and in a moist condition.

The physiologists state that the function of the prepuce is to cover the glans and protect it from vicarious irritation. It does not appear, however, that contact with the outer world does it any harm or that the circumcised races are any less fertile than the uncircumcised. In the event of subsequent urethral infection the absence of the glans covering is certainly an advantage from the point of view of both diagnosis and treatment.

Circumcision without an anaesthetic is a somewhat barbarous procedure, and any anaesthetic is a potential danger and entirely undesirable in an infant unless it is absolutely unavoidable. The enormous number of entirely unnecessary circumcisions that are done in infancy is nothing less than deplorable. It is thoroughly bad surgery to remove anything, whether it be a foreskin or a tonsil, unless one has definite reasons for doing so.

CONCLUSIONS

1. Circumcision is never necessary in the newly born as a primary procedure—and very rarely necessary at all.
2. Dilatation and retraction of the foreskin in these cases is easily and rapidly carried out; it requires no anaesthetic, and is extremely satisfactory.

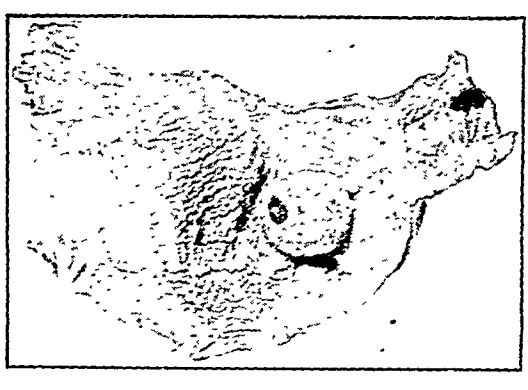
Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

HAEMORRHAGE AND DEATH FROM A GASTRIC MYOMA

Innocent tumours of the stomach are not common, and death as the result of one of them must be a rare phenomenon. Eusterman and Senty[1] estimate that malignant tumours of the stomach are seventy-eight times as common as innocent tumours. Of the latter they find that myomata are the commonest. Haemorrhage is stated to be a rare complication; pyloric obstruction (due to the ball-valve action of a polypoid growth), intussusception of the stomach into the duodenum, strangulation, and malignant hyperplasia being more frequently met with. These writers record haemorrhage in ten cases out of twenty-seven described, but not to the extent of causing death in any one. Miodowski in 1901 recorded a case of a woman, aged 51 years, who had been ill with marked abdominal pain and melaena for six weeks, when she died from a recurrent haemorrhage from the ulcerating surface of a polypoid gastric myoma. This case bears some resemblance to that about to be described.

[1] Eusterman and Senty: *Surgery, Gynecology and Obstetrics*, 1922.



Clinical Notes of Case

A woman, aged 54, was admitted to hospital on July 22nd, 1930. She stated that she had enjoyed normal health until six months prior to admission, when she suddenly vomited about a pint of bright red blood. This did not recur; but for ten weeks after her stools were dark and tarry. During this period she became progressively paler. She remained in this condition until four days before admission, when she became very faint, and the dark stools reappeared. Apart from one attack of haematemesis she had never vomited. There had never been any abdominal pain or discomfort or nausea at any time, and her appetite had remained good throughout her illness.

On physical examination she was found to be very pale but well nourished. Her pulse rate was 120, and her temperature subnormal. There was slight rigidity of the upper half of the left rectus muscle, and the stomach was made out to be dilated. A haemic murmur was heard over the precordium, otherwise there were no physical signs of note. The melaena persisted and became more marked until her death five days after admission. Blood count: red blood corpuscles, 2,600,000 per c.mm.; white blood corpuscles, 5,600 per c.mm.; haemoglobin, 25 per cent.

Post-mortem Findings

At the post-mortem examination a soft spherical tumour, about the size of a tangerine orange, was felt in the lumen of

the stomach, projecting from its lesser curvature by a sessile base. There was a large quantity of altered blood in the stomach and in the whole of the intestinal tract. All other organs were normal.

Pathological Report

I am indebted to Dr. J. B. Duguid, acting professor of pathology in the University of Wales, for the following pathological report: "On the anterior wall of the stomach, about midway between the greater and the lesser curvatures (see photograph), and about one and a half inches from the pylorus, there is a spherical tumour projecting into the lumen of the stomach. This tumour is about one and a half to two inches in diameter, and attached by a base about one inch in diameter. It is covered by mucous membrane except at two points: one at the summit of the outgrowth, and the other near the base on the cardiac side. At these two points there are punched-out ulcers with slightly overhanging margins. Each one is about a third of an inch in diameter, and about a quarter of an inch in depth. Their internal surfaces are ragged and necrotic, and at the base of the former there are two patches of haemorrhagic discoloration representing the points of origin of the haematemesis. The ruptured vessels cannot be seen by the naked eye. Histologically the tumour is a leiomyoma of entirely typical structure."

DAVID G. MORGAN, M.R.C.S., L.R.C.P.,
First Assistant Medical Officer, City Lodge Hospital, Cardiff.

Reports of Societies

TREATMENT OF INOPERABLE CARCINOMA OF THE BLADDER

At a meeting of the Section of Urology of the Royal Society of Medicine on June 25th, with the president, Mr. S. G. MACDONALD, in the chair, Mr. R. OGIER WARD opened a discussion on the treatment of inoperable bladder carcinoma.

He said that there were no means by which it could be decided that a bladder growth was operable—that is, curable by operation—with the accuracy obtainable, for example, in gastric cancer by careful investigation and later exploration by laparotomy as to the extent and relationships of the growth. Fortunately, in bladder carcinoma, the determination of the presence or absence of glandular involvement or secondary deposits had not the same immense importance as in the treatment of cancer elsewhere, for the reason that operative excision of the primary growth was always, in the speaker's opinion, the best treatment if it could be carried out. In the squamous-celled ulcerative growths and the nodular infiltrating type of carcinoma—he was not speaking of papillomata for the moment—the most important thing to decide, assuming that the patient was judged fit enough to survive the operation, was the practicability of removing the entire growth from the bladder, with a reasonable chance of non-recurrence. There was no simple palliative operation for carcinoma of the bladder which gave results in any way comparable with those obtained from colostomy in rectal cancer. Broadly speaking, he regarded as definitely inoperable (using this word now without special reference to cure) those bladder growths which were found on bimanual examination to be fixed; also, if a simple rectal examination revealed a hard mass more or less continuous with the prostate, it was most unlikely that an operation could be performed. Size alone was not a contraindication to excision. If the cystoscope revealed any useful margin of healthy mucosa surrounding the neoplasm, then, subject to the conditions just mentioned, he thought that in very many cases of infiltrating bladder cancer excision was possible and useful, even when it could obviously give no hope of cure.

Radium had its place in treatment, but if one believed excision to be the best procedure, it followed that in the case of growths which were ulcerative and infiltrating, radium would be used only when there already existed considerable and indeterminate extensions of the disease, both into the walls of the bladder itself and the tissues outside. From 1927 until the end of 1930, Mr. Ogier Ward said, he had treated by radium forty-three cases of bladder growths and had followed up most of them. Out of fifteen patients treated by radium applied at open operation twelve had almost certainly died, and he did not know that any of them had lived for more than twelve months; the other three had to some extent benefited. In these fifteen cases there were very extensive growths, so that the failure of radium in this respect was no evidence as to its general value in treatment. At the Radium Institute he had had opportunities of treating bladder growths with seeds containing radon, which he had introduced through a cystoscope. The method, though of limited application, had more practical value than might at first be supposed. He had often inserted ten or twelve seeds with fair accuracy, and occasionally had used as many as thirty at one sitting. The seeds were 6 mm. in length and 1.1 mm. in diameter, with an average strength of 1.3 to 1.7 millicuries, and the radon was contained within a minute sealed capillary glass tube in a platinum case 0.3 mm. in thickness, which provided a supporting sheath as well as screenage. This method had been employed in eight patients with ulcerative and with nodular infiltrating carcinoma; in all of them excision was impossible. Of this number four or five had died, none were cured, and three had benefited, one only slightly and two definitely. One of these, which he described in detail, showed quite remarkable improvement. In this case seeds had been passed through the prevesical tissues down to the deep aspects of the growths seen with a cystoscope; the exact position of the point of the introducer could thus be seen and controlled with accuracy. Nine cases of villous carcinoma had been treated with radon seeds, and of these five had so far shown no recurrence. Nine cases of vesical papilloma had also been treated. The average age of these patients was just over 60, and their growths were all of a doubtful nature. In four cases it appeared possible that a cure had been effected, while two more seemed to have benefited. To sum up, if it was agreed that, when possible, infiltrating growths should always be excised, then radium as a means of treatment for these would be used only if such an operation could not be carried out. The results then aimed at would be only palliative, and seeds introduced through the cystoscope might be useful for this purpose. He thought also that in dealing with villous carcinomata and papillomata, operable as well as inoperable, there was a place for this form of treatment.

Mr. Ogier Ward briefly considered other forms of treatment for inoperable bladder growths: diathermy; deep *x*-ray therapy; cystotomy (only usefully employed to prevent attacks of clot retention in the bladder); and total cystectomy with transplantation of the ureters. This last was a palliative measure which might afford relief, although it was a suggestion unlikely to be accepted by the patient until all hope of cure was past. He concluded with some remarks on the section of nerve tracts, designed to relieve the terribly severe pains suffered by patients in their latter days. The simplest method was the operation practised in selected cases by Cotte of Lyons, for the relief of dysmenorrhœa and some other female pelvic disorders—namely, the division of the presacral nerve. Recently, at the clinic of Professor von Lichtenberg, Mr. Ward was shown a case of prostatic carcinoma rather far advanced, which had infiltrated the bladder wall and surrounding tissues. Division of the presacral nerve was carried out, and the constant pain which had been radiating down both sciatic nerves was entirely relieved. He himself had performed this operation in three cases within the last month. The exposure of the tissues lying over the body of the fifth lumbar vertebra was probably easier in the female than in the male, but such difficulty as was met with was chiefly due to the amount of extraperitoneal fat with which the hypogastric nerve plexus and the presacral nerve were surrounded and the proximity of the inferior mesenteric vessels. In these three cases he had succeeded in excising a length of nerve tissue varying from 1/2 inch to 1¼ inches. The outstanding feature of the results was that the urgency and frequency of micturition had been markedly reduced. He also mentioned the method of chordotomy as one which had been employed for the relief of very severe pain due to pelvic lesions, and seemed to be ideal for hopeless cases of bladder growth. In this operation, which was rather more severe than the one just mentioned, the neighbourhood of the ninth dorsal segment of the spinal cord was exposed by laminectomy, and both antero-lateral tracts divided; these contained the spino-thalamic tracts, which conducted sensations of pain, heat, and cold. This operation should result in almost certain relief of pain for the remainder of the patient's life.

Mr. KENNETH WALKER expressed his pleasure at the choice of this difficult subject for discussion, as the

sufferings of patients who had inoperable carcinoma of the bladder were frightful, and everything possible must be done to relieve their agony. His experience of radium needles in these cases had been discouraging, though he had not often used radon seeds. He concentrated on the relief of the patient's pain. To this end, division of the presacral nerve seemed to be a method worth pursuing. He related the case of a doctor in whom chordotomy was successful in freeing him from pain; he had carcinoma of the prostate, which later extended to the bladder. The disadvantage of the operation of chordotomy was that it was a severe and separate operation; it could not be carried out at the time of the exploration. There were severe cases of pain in which it was difficult to know where it originated, and possibly division of the presacral nerve would not always relieve pain. He supposed that one would be safe in operating in all cases in which the complaint was of pain on micturition only, not of persistent pain apart from micturition.

Mr. FRANK KIDD said that his impression was that the pain in these cases was due chiefly to spasm of the bladder wall rather than to pressure on nerves deep in the pelvis. That was the reason why cutting of the hypogastric nerves relieved pain—that is, by relieving tension. Real progress in these distressing cases in future would be along the lines of implantation of the ureters into the rectum; he was trying to improve the technique of this operation so that it could be done quickly. Removal of the bladder would not then be such a serious operation.

Mr. CYRIL NITCH said that he had had fourteen cases in which transplantation of the ureters had been done, in seven of them for practically inoperable carcinoma or other malignant growth of the bladder. In the carcinoma cases he had done it in the hope of being able to perform total cystectomy. The seven patients who had had bladder carcinoma had all died, while the other seven—that is, the non-malignant cases—had recovered.

Mr. E. W. RICHES thought that two main types of growth must be recognized; the first and the less common was the flat epitheliomatous ulcer, and the other more common type was characterized by hypertrophy. The first of these caused earlier metastasis than the second. Some believed that the papillary type, which gave local recurrence, was non-malignant, but section of such cases showed invasion of subjacent tissues, or transgression of basement membrane, and he regarded the condition as carcinoma. Prognosis and treatment differed in the two types. The flat type was more amenable to radium than the other.

Mr. J. P. ROSS said that division of the presacral nerve was a more selective type of operation than chordotomy, as it was clear that, if successful, it would relieve the bladder pain without interfering with sensation in the rest of the body. Chordotomy, on the other hand, removed sensation from all parts below the level of the nerve section, and it might be a disadvantage to give a patient anaesthetic legs. As the operation produced a certain effect in cases of severe pain which could not be relieved by any other means, it had a definite place in surgery.

Mr. JOCELYN SWAN said that in the papillary form of carcinoma one could do much more by extensive diathermy through a suprapubic opening than with radium. He had had a number of cases in which on opening the bladder he had found a large growth, of which he had been able to remove the fungating portion by diathermy, and then remove the base by the endothermy knife, transplanting the ureter as was necessary. In some cases he was content to do extensive diathermy to the whole base of a papillary carcinoma, and he had been surprised at the extent to which this relieved both pain and haematuria. He had reserved radium for the infiltrating epitheliomatous types of ulcer in the bladder. In his earlier work with radium he was disappointed, because he had caused more pain than the patient had suffered before, and there had been extensive sloughing, which had continued for some time. That had been because he had used too heavy a dose. Now that he used lighter doses the pain was not so great, but the results were less good. He had transplanted the ureters in several cases of inoperable malignant disease of the bladder, and in two cases particularly the relief of pain had been marked, but the malignant disease had remained, and the patients had died eventually of metastasis from the carcinoma, not from ascending nephritis. In transplanting ureters it was better to do one at a time. In several cases which had secondary deposits he had used the radium "bomb," but could not say that he had seen a good result.

COLOUR VISION: YOUNG'S THEORY

The Thomas Young Oration, entitled "Young's theory of colour vision," was delivered by Sir JOHN H. PARSONS, F.R.S., before the Optical Society on June 11th.

Sir John Parsons began by remarking that although Thomas Young was well known as the founder of a theory of colour vision, his contributions to the theory were limited to two or three short paragraphs, and there was no evidence that he himself attached much importance to them. He was the first who, starting from the well-known fact that there were three primary colours, sought for the explanation of this fact, not in the nature of light, but in the constitution of man.

Although the three-component theory, as developed by Clerk Maxwell, Helmholtz, and others, accounted well for many of the facts of colour mixture, it had also to account for other phenomena of vision, such as visual acuity, the luminosity curve, hue discrimination, simultaneous and successive contrasts, and colour blindness. Recent work by Hecht and others had succeeded in solving many of these phenomena. The determination of the luminosity curve, which physicists still persisted in calling the "visibility" curve, had been the subject of such accurate investigation that it could now be regarded as one of the soundest scientific data in the whole realm of vision. Dalton might be regarded as initiating the scientific study of colour vision, and later work by Seebeck and Clerk Maxwell strongly supported the view expressed by Young that cases of colour-blindness were reduced forms of normal vision. On this theory the neutral points of the spectrum as seen by protanopes and deuteranopes were excellently explained by the points of decussation of their two remaining curves. The fact that yellow was psychologically as distinctive a colour as red, green, or violet, and physiologically showed no evidence of composite character, was long regarded as a strong argument against the trichromatic theory until Hecht proved conclusively that the sensation of yellow could be experienced by fusing binocularly the sensations produced by appropriate red stimulation to one eye and green stimulation to the other.

Research since Young's day had done nothing to bridge the gap between the physiological and the psychological response, but considerable progress had been effected by Holmgren, Kohlrausch, Lucas, and Adrian in elucidating the physiological response itself. The results of these workers on the photo-chemical reaction of the visual purple, and the accompanying changes in electrical potential of the retinal structures, all tended to show that the fundamental phenomena of vision manifested themselves in the retina. Finally, the researches of Pieron, especially those on colour responses to black and white stimuli, and those of Allen on induction effects as shown on the persistency curves resulting from previous stimulation of the retina by monochromatic light—all these had a distinct confirmatory bearing on Young's theory.

Reviews

INJURIES AND SPORT

Dr. C. B. HEALD describes his new book, *Injuries and Sport*,[1] as a general guide for the practitioner, and this it may fairly claim to be. It is interesting and important, as, curiously enough in this sport-loving land, so far as we are aware, the claim made in the preface—that this is the only work of its kind written in English—is justified. As such it should prove of real value to medical men in hunting districts or in charge of public schools, sports clubs, etc., who are constantly called upon to treat minor, and occasionally major, injuries. It is as a guide to the discrimination between these that the book will be found most useful, because the description of each region is wisely divided into two parts—diagnosis and treatment—and Dr. Heald emphasizes more than once how fallacious is the common idea that an injury to soft parts is less serious and disabling than one to bone. We have the feeling that this is an honest book, which attempts to show exactly how far physiotherapy can go in the treatment of injuries, and at what stage more drastic surgery is called for. In this respect the book is singularly free from errors, and the potentialities of operation are frankly recognized. A curious exception to this rule is the complete lack of recognition of operation as an almost certain cure for recurrent dislocation of the shoulder.

We read the various sections on electrotherapeutics with great interest. The author has a wide knowledge of this branch, and, wonderful to relate, makes no effort to wrap up this knowledge in mediaeval mysticism. On the contrary, he describes the various currents in simple language, and, furthermore, tells how they may be produced with simple and inexpensive apparatus, and employed by, or under the direction of, the general practitioner. Further still, he explains in simple words the supposed action of each current and the consequent physiological indications for its use. In this latter connexion the inclusion of an introductory chapter on the physiology of repair is intelligible. At first sight it would seem to have a better place in a student's textbook—which, frankly, this is not. The busy practitioner has passed that stage, and has absorbed the teaching if he has forgotten the details ; but, as anyone attached to a medical school must feel, the point cannot be stressed too often that intelligent treatment of injury is impossible unless the practitioner visualizes the pathology of the affected structures at all stages of treatment.

In the Air Force Dr. Heald had large experience of the immediate treatment of serious injury. This part of the book is excellent, and so also is the chapter on the factors modifying recovery from injury—a true branch of orthopaedic "medicine." Some people, perhaps, will consider that treatment by anodal galvanism is unduly stressed, and that Dr. Heald claims too much for this method. It is said that the results are not commensurate with the trouble involved. In the opinion of the present reviewer this is not so ; and, in any case, it is made clear that the trouble is very small. The employment of other forms of electrotherapy is a less controversial subject. In the section on massage, local hypnosis (after the teaching of Lucas-Championnière and Mennell) is advocated as a routine treatment for injuries. The successful employment of this method depends, as does all hypnotism, so much on the personality of the therapeutist that, in our opinion, it is not suited to general use, however efficient it may be in the hands of the expert. In Part II, which is a regional description of the methods advocated in Part I, modern uses of splints and plaster are well described, in addition to physiotherapy, and the synopsis in Appendix II is a welcome innovation.

The preface indicates, and the whole book elaborates, the importance of team-work in the treatment of injuries, as is true of all modern therapeutics, and Dr. Heald may be congratulated on his balanced view of the relative merits of the methods at our disposal. The book is well printed, and illustrated by excellent photographs, both of treatment and of the actual ways in which injuries occur in the field. We can especially commend the diagrammatic index, which is conveniently found at *both* ends of the book.

LABORATORY DIAGNOSIS

There is now no lack, either for the graduate or undergraduate, of textbooks on laboratory diagnosis. Dr. DANIEL NICHOLSON of Winnipeg is the author of the latest work[2] on this subject. In the preface he explains that his aim is not only to give in detail the indications, methods, and interpretation of useful tests that all medical men should be able to perform, but also to outline the principles and interpretation of tests which can only be carried out adequately in a large and specially equipped laboratory. Dr. Nicholson is obviously an enthusiast, both as a laboratory worker and as a teacher, and his whole heart goes into this book, which is written in a highly individual way. It is not unfair to say that the influence of the neighbouring United States of America shows strongly in this book, and here in Britain it would be absurd to expect the general practitioner to attempt by himself many of the laboratory methods described as suitable for his unaided performance. The practitioner who likes to do most of his own laboratory work will, however, delight in this book, and it is, indeed, chiefly for such men that it has a special appeal. Chapter XIV, on the equipment of a simple home-made clinical laboratory, is excellent, even though the only sources of purchase of laboratory supplies given are not even Canadian, but in Pittsburgh and Philadelphia! For the established laboratory worker and the physician already well trained in laboratory methods this work is useful, but it has no advantage over many others that are already available. The author, like all of us, has his decided preferences for some methods, but on the whole his choices are good. Certainly there is never any lack of clearness in the author's mind about what should be done in given clinical circumstances. The book is not likely to have a great sale in Britain, but we wish it every success in Canada and in the United States. The author, who is a member of the Royal College of Physicians of London, must be well aware that the circumstances of medical practice here differ from those with which he is now most familiar.

PERIPHERAL VENOUS PRESSURE

Whereas arterial blood pressure readings have long been a matter of routine, the estimation of peripheral venous pressure,[3] on which Professor MAURICE VILLARET and his collaborators, Drs. F. SAINT GIRONS and L. JUSTIN-BESANÇON, have brought out a monograph, has not become popular in ordinary practice, and, indeed, seems unlikely to rival that of arterial blood pressure, although the literature on the subject, as shown by the authors' bibliography of seventeen pages, is far from scanty. There are two main ways of taking the pressure in the peripheral

[3] *La Pression veineuse périphérique. Étude physiologique, clinique, et thérapeutique.* Par Maurice Villaret, Fr. Saint Girons, et L. Justin-Besançon. Paris: Masson et Cie. 1930. (Pp. 318 ; 17 figures. 38 fr.)

veins: the indirect method described by a number of writers, such as Hooker and Eyster, Oliver and von Recklinghausen, in which the veins are compressed by a measured weight; and the direct method, after Stephen Hales and François-Franck, in which the intravenous pressure is estimated by means of a trocar introduced into the vein. The latter gives far more accurate results than the indirect method, which is chiefly useful when a number of estimations are made on the same person at different times and so can be compared with each other. Professor Villaret's phlebopiezometer, invented in 1920, shows that the normal intravenous pressure at the bend of the elbow taken in the horizontal position is 13 cm. of water in men and 12 cm. in women, pressures above 14 cm. being hypertensive and below 11 cm. hypotensive. The physiological aspects of blood pressure in the peripheral veins are discussed at length, and attention is directed to the factors influencing it, such as the state of the ventricles of the heart, the arterial blood pressure, the small vessels and capillaries, and the veins. It is only in comparatively recent times that investigation has been undertaken to elucidate the influence of venous pressure in the superficial veins on the circulatory system—for example, on the activity of the heart, and the relation between the pressure in the splanchnic vessels, such as portal congestion, and that in the superficial veins. The account of the condition of the peripheral venous pressure in various diseases is rich in personal observations, and the results are recorded under the headings of cardiac disease, obstruction of the superior and inferior venae cavae, portal and pulmonary venous obstruction, cyanosis, diseases of the blood-forming organs, acute infections, and so forth. This monograph is a most useful source of reference.

AN AMERICAN EXTRA PHARMACOPOEIA

We have received the fifteenth edition of POTTER'S *Therapeutics, Materia Medica, and Pharmacy*.[4] This edition, like its recent predecessors, is edited by Dr. R. J. E. SCOTT. In its scope the volume somewhat resembles the well-known *Extra Pharmacopoeia* of Martindale and Westcott, for the preface states that "the work is intended to serve as a compendium of information regarding both official and non-official drugs and preparations. It is not to be inferred that the mention of any drug or preparation necessarily carries with it any endorsement." A reasonable selection has been exercised to avoid devoting undue space to obsolete drugs, but on the whole the volume is encyclopaedic rather than selective.

The book is divided into two main sections—namely, materia medica and therapeutics—and in addition there is a smaller section devoted to pharmacy, prescription writing, incompatibilities, etc. The materia medica section resembles the *British Pharmaceutical Codex* in its general scope and arrangement. In the case of each drug an account is given of all its important preparations, and this is followed by a short article on its physiological and therapeutic action. In the therapeutic section the disorders and diseases are arranged alphabetically and a list is given of the chief remedies that are recommended by standard authors. The only disadvantage of this method is that in the case of some diseases considerable sections of the pharmacopoeia are reproduced—for example, forty remedies are mentioned for pertussis, thirty-seven for asthma, and thirty for scarlet fever. It seems doubtful whether the practitioner is likely to be greatly helped by being presented with such an embarrassingly wide choice.

The introduction contains an interesting sketch of the history of therapeutics. Incidentally the author points out a fact that is often forgotten—namely, that Hahnemann made a serious endeavour to establish a rational system of therapeutics based on experimental evidence. Unfortunately he made broad generalizations from certain observations whose significance he misunderstood, and in the end the sound fundamental conception was hidden beneath a superstructure of absurdities. This tragic ending to the first attempt at systematic pharmacology undoubtedly delayed the development of scientific therapeutics for the greater part of a century.

THE CARE OF THE CHILD

The Child and His Home[5] is a characteristically American production. It is by Dr. H. W. HURT, who is described as "Director of Research for fourteen committees at President Hoover's White House Conference on Child Health and Protection." His book is said to be "based upon the important conclusions reached at that conference," and to contain "practical contributions to child culture from modern research." It is dedicated to President Hoover as "the visioned proponent of that gift within Democracy's power—a chance for every child." It is prefaced by the nineteen sections of "The Children's Charter," which appears to be the result of the conference referred to, and which embodies, in a somewhat grandiose manner, what we in this country would regard as the ordinary claims of childhood to consideration and to help in the home, the school, and the community. It appears that at this conference a number of people formally pledged themselves to secure "for every child these rights regardless of race or colour or situation wherever he may live under the protection of the American flag." This is all to the good, and may have been necessary in the conditions of the United States of America, which, from some of the facts given in this book, seem in certain respects to be appalling; but in Great Britain these needs have now been universally recognized for many years, and practical steps have been quietly and progressively taken to supply most of them. The "important conclusions" which call loudly for the "child culture" of the "citizenry" are that the environment of a sensible and normal family life is good for a child, that parental responsibility is great and should be properly exercised, that due attention should be paid to diet, health, and recreation, that he should be suitably and carefully educated, protected from accidents, and cared for if he is physically or mentally defective. These are here accepted as commonplaces, and, though a large number of facts and statistics about American life and conditions are given in Dr. Hurt's chapters, they result only in generalizations which are of scarcely more practical value than those set out above. It is, of course, interesting to know that "census records tell us that one marriage in six ends in divorce," and that "samplings show one child in three in broken homes"; that "a family living in one room as contrasted with four rooms meant five inches less in height and 12.9 pounds less in weight"; that the population consists of a conglomerate of negroes, Asiatics, and the various races of Europe in such and such proportions; that urban churches average so many more members and spend so many more dollars than rural churches; that "the motion picture purveys visual and auditory representations to a world audience of 225,000,000 a week," and so on. We know that all these things, and many other things that Dr. Hurt tells us, of which these are a fair sample, have their bearing,

[4] *Therapeutics, Materia Medica, and Pharmacy*. By S. O. L. Potter, M.D., M.R.C.P. Fifteenth edition, revised by R. J. E. Scott, B.C.L., M.D. New York. Philadelphia: P. Blakiston's Son and Co., Inc. 1931. (Pp. xv + 997. 8.50 dollars.)

[5] *The Child and His Home*. By H. W. Hurt, Ph.D. New York: Minton, Balch and Co.; London: G. P. Putnam's Sons. 1931. (Pp. xiv + 260. 10s. 6d. net.)

direct or indirect, on child life. But the volume as a whole can scarcely be said to be very helpful, and this is not compensated for by any merits of style or presentation.

HALLIBURTON'S "PHYSIOLOGY"

Only two years elapsed between the publication of the eighteenth and nineteenth editions of the ever-popular *Handbook of Physiology*,[6] with which the late Professor Halliburton identified himself for so many years. When reviewing the previous edition (*Journal*, 1929, i, 815) attention was drawn to the remarkable history of this work since its first appearance as Kirkes's *Physiology* in 1848. The last two editions, with which Professor McDOWALL has been associated as joint author, portray clearly the change in the general outlook of physiology during recent years; the old anatomical basis is now receding into the background, while the body as a whole has to be "considered more from the point of view of physiological processes rather than of the functions of isolated organs." A new chapter on sensation, bringing together various topics hitherto scattered, illustrates an advance in co-ordination which breathes the spirit of modern times. One surprising discovery is that the present edition is slightly smaller than its forerunners, much of the detail of the histology of the connective tissues and descriptions of elementary electrical apparatus being now omitted. The index has been completely revised, and one change which will be greatly appreciated by students is the use of bold type for those figures which have to be committed to memory in preparation for examinations. A few new illustrations have been added. The whole volume can be commended, not only as an up-to-date review of physiology, but also as a most helpful introduction to its clinical application.

NOTES ON BOOKS

The seventh volume (*Magenkatarrh-Nasenkrankheiten*) of the New German Dictionary of Practical Medicine,[7] edited by Professors GEORG and FELIX KLEMPERER, contains the following articles by well-known authorities: gastric catarrh, by Professor F. Kauffmann of Berlin; cancer of the stomach, by Professor I. Boas of Berlin; surgical treatment of gastric and duodenal cancer, by Professor H. von Haberer of Cologne; gastric neuroses, by Professor Gerhardt Katsch of Greifswald; malaria, by Professor P. Mühlens of Hamburg; manic-depressive insanity, by Professor Hans W. Gruhle of Heidelberg; measles, by Professor R. Degkwitz of Greifswald; massage and therapeutic gymnastics, by Dr. F. Kirchberg of Berlin; diseases of rectum and anus, by Dr. Max Marcus of Berlin; foot-and-mouth disease, by Professor H. Hetsch of Frankfort; mediastinal diseases, by Dr. W. Beck of Berlin; meningitis, by Professor E. Le Blanc of Hamburg; menstruation and its disturbances, by Professor R. Schröder of Kiel; miliary tuberculosis, by Dr. Gustav Liebermeister of Düren; anthrax, by Professor Hetsch; diseases of the spleen and haemolytic jaundice, by Professor G. Klemperer and Dr. Paul Radt of Berlin; morphinism and allied alkaloid addictions, by Dr. P. Wolff of Berlin; mumps, by Dr. W. Keller of Heidelberg; muscular rheumatism, by Professor F. Schultze of Bonn; myelitis, by Dr. Eugen Pollak of Vienna; myopathies, by Professor Hans Curschmann of Rostock; myxoedema, by Professor A. Gigon and Dr. O. Merkelbach of Basel; food intoxications, by Professor Schwarz; food intoxications of bacterial origin (paratyphoid, botulism, Bang infection), by Dr. Hans Schulten of Hamburg; and diseases of the nose, by Professor G. Finder of Berlin.

A small book on the clinical aspects of the thermal waters of Dax[8] has been prepared by Drs. LOUIS and RENÉ LAVIELLE, with a preface by Professor BABINSKI. Here will be found an account of the methods of treatment carried out at Dax, and the indications and contra-indications for the "cure."

The fifth issue of the *International Health Year Book*[9] is considerably larger than its predecessor (see *Journal*, February 1st, 1930, p. 205), as it contains particulars of the health progress of eleven more countries. The same arrangement of the vital and nosological statistics is adopted as in the previous volume. The section devoted to the United Kingdom is divided into three parts, relating to England and Wales, Scotland, and Northern Ireland respectively, in each of which details are given of vital and public health statistics, the prevention and treatment of infectious diseases, and public health activities.

The small book by ETTIE A. HORNIBROOK on *Restoration Exercises for Women*[10] purports to prescribe a series of general exercises for the preservation and restoration of woman's body, with special exercises for the feet; and with an appendix on diet in constipation. Exercises are also described for use during pregnancy. Mrs. Hornibrook takes for her models the dances of certain savage peoples, considering that "the best thing for us to do is to adopt a system of exercises based on native dances, because these dances are themselves the concentrated form of the natural movements of fishes, lizards, birds and mammals, bipeds and quadripeds." Without admitting the validity of all the author's contentions, we think that there is something in the notion. At any rate, the exercises described and recommended are likely to be beneficial. The dietary for constipated persons should also be useful, even if constipation is not to be credited with all the dire effects which the author and some others attribute to it.

The first volume of the forty-first series of *International Clinics*[11] contains clinical papers by Professor Lewellys F. Barker of Baltimore, and the members of the medical department of Emory University, Atlanta, Georgia, a section on the clinical applications of biochemistry, and short articles dealing with recent progress and important developments in medicine, obstetrics, paediatrics, and surgery by the editor and others.

The fifty-fifth volume of the *Transactions of the American Gynecological Society*[12] provides a full record of papers and discussions in the scientific sessions of the annual meeting held in May, 1930, at Hot Springs, Virginia, under the presidency of Dr. Charles C. Norris of Philadelphia. The text is illustrated by reproductions from photographs.

We welcome the tenth issue of the French Medical Annual,[13] edited by Dr. CAMILLE LIAN, with the assistance of thirty-four contributors, who are the same as in the previous year (see *Journal*, June 14th, 1930, p. 1098). The summaries of recent work are concise and clear, but are mainly based on French contributions to medical literature, while foreign publications, particularly British, receive comparatively little attention. An index for the issues 1926-30 inclusive is appended.

THE COLONIAL MEDICAL SERVICES

Thanks partly to the film industry, but chiefly to the poster activities of the Empire Marketing Board, the early prejudices against the Tropics created in the mind of the general public by the title of Stanley's *Darkest Africa* have been replaced by bright pictures of cocoa groves and banana plantations, and a lively appreciation of the political significance and economic importance of the increasing dependence of the Home Country upon the development of the food resources of our colonial Empire. With the enormous economic expansion of our tropical Dependencies and the material improvement of conditions of life therein, colonial Governments have felt an increasing sense of responsibility for the welfare of the native peoples, and in recent years have sought to provide many of those services which at home are supplied by municipal and private enterprise. There have been ever-increasing calls for the protection from disease, not only of human life, but of stock and of crops. This demand has led to a great increase in the staffs of the medical and scientific departments of the colonial Services and for a higher standard of personal and professional qualifications, so that to-day the colonial Services rank among the premier Services of the Empire, and call annually for over a thousand candidates for medical and scientific positions of great interest and responsibility.

The need for specialized training which Manson foresaw when he advocated, a quarter of a century ago, the creation of special schools of tropical medicine has since been realized in other directions, notably in the creation of the Imperial Institute of Entomology, the Imperial Mycological Institute, the Imperial Institute of Tropical Agriculture, and in the recent institution of the Imperial Agricultural Bureaux ; while the Lovat Committee on the reorganization of the Colonial Veterinary Services recommended the establishment in London of a post-graduate school of tropical veterinary science on the lines of the London School of Hygiene and Tropical Medicine. But of recent years there has been increasing realization of the fact that further advance in the control of tropical diseases is largely dependent upon fuller recognition that much tropical disease is disease in the Tropics ; that the fundamental principles underlying the control of disease at home and in the Tropics are the same, and that the practitioner and medical officer of health at home should learn something regarding those diseases which prevail in the Tropics and which, with the ever-increasing facilities for rapid transport, may come at any moment under his notice.

Appreciation of what science can do for economic expansion is not, however, in itself a sufficient basis for the development of scientific services, and facilities for special training will be fruitful only in so far as they afford access to a field of practice calculated to attract candidates competent for the twofold task of enlarging the common stock of knowledge and giving it practical application. To this end work itself must not lack interest, and should be varied enough to afford scope to diverse types of ability. Economically, it must offer a general standard of life not inferior to the average enjoyed by the main body of the profession, with opportunities for advancement comparable to those attached to other branches of practice. Ethically, there must be no infringement of professional standards and no lay interference in the discharge of professional functions ; and, on the material side, adequate equipment must be available for the efficient performance of allotted duties. Failure in any one of these respects will inevitably react upon the supply of recruits. Now, as in Manson's day, tropical practice is not lacking in intrinsic interest, and "in all pathology there is no such field for fruitful original research and discovery as tropical medicine," nor is there any specialty of which it can be said that the Tropics provide no field for its practice. On the other hand, scientific medicine is not an indigenous growth in the Tropics, and the effective economic demand necessary to the development of private practice has been to a great extent lacking for obvious reasons. The main burden of the provision of medical services has therefore fallen on the colonial administrations, and it is not unnatural if from time to time there has been a failure to adjust service conditions to legitimate professional demands. The consequent difficulty in recruiting has given the British Medical Association its opportunity to explain those demands, to indicate methods of meeting them, and to assert the fundamental unity of the interests of those in practice over-seas and at home. The manner in which it has done so is described in the special *Colonial Medical Supplement* which we publish to-day.

The story of the activities of the Association on behalf of the profession over-seas in the past will, we feel sure, be read with interest and gratification by members of the Association at home. Those abroad will recognize more fully, perhaps, the peculiar difficulties in which the Association has often had to act in maintaining their rights and privileges, and it is to be hoped that our *Supplement* may lead to an increased appreciation of the effectiveness of the support which the Association can give through the weight of professional opinion it can mass in support of those of its members who are faced with special problems, either as members of a Government staff or as medical officers employed by commercial enterprise.

UNEQUAL LEGS

We print this week Professor Ernest Hey Groves's lecture on stature and pose, which he gave to the Royal Free Hospital Medical Society on a recent occasion. The valuable lessons he teaches resolve themselves into practical advice as to the best ways of correcting inequality in the length of the lower limbs from whatever cause it may arise. Even at the present time,

when the treatment of tuberculous joint disease has so much improved, and prevention of deformities in general has made such strides, there are, unfortunately, many limbs which, had early orthopaedic treatment been available, would be equal, or, if not quite equal, much less disproportioned than they are. Gant's introduction of subtrochanteric osteotomy of the femur, more than half a century ago, put into the hands of surgeons a means of correcting many short limbs resulting from ankylosis of the hip in an adducted and flexed position, but the number of cripples still hobbling about on high cork boots is evidence that full advantage has not hitherto been taken of Gant's operation. This is probably due less to want of enterprise in surgeons than to the reluctance of patients, who probably have had long experience of operations, once more to occupy hospital beds and undergo the procedures made necessary by the incompleteness of their original treatment.

Professor Hey Groves prefixed to his lecture a question quoted from the Sermon on the Mount. The question was, of course, a rhetorical one, for although when stated in Hebrew standards of measurement, the increase implied may seem modest, when translated into inches it is at once evident that an increase of eighteen inches in height would transfer the average man into the ranks of the greatest known giants. But the question, "Can a man add an inch or more to his stature?" is nowadays not a rhetorical one, and demands an answer in the affirmative. The lecturer's choice of subject was a peculiarly happy one, for the pioneer of osteotomy for ankylosis of the hip in a vicious position was undoubtedly Frederick James Gant, surgeon to the Royal Free Hospital. We say advisedly "the pioneer" because, although William Adams preceded him in the introduction of osteotomy of the neck of the femur, his method was not found applicable to very many cases of ankylosis. The great superiority in principle of Gant's operation consisted of the choice of a site below the insertion of the ilio-psoas, so that the difficulties of correction and the likelihood of recrudescence of deformity were very greatly diminished. Gant's paper, which was a really epoch-making one, was read at the Annual Meeting of the British Medical Association at Cork in 1879. Its title was, "On subcutaneous osteotomy below the trochanters."[1] Subcutaneous surgery has now lost its importance, but the principle upon which Gant's operation was devised applies with equal force to osteotomy through an open wound.

The lecturer classified cases of short lower limbs into four main categories, due to (1) malunion of fractures, (2) faulty ankylosis of the hip-joint, after infectious arthritis, (3) poliomyelitis, and (4) congenital or pathological dislocation of the hip. Of these the second is far the most important in its frequency and the severe degrees of shortening which characterize the vicious attitude. Some surgeons would add a fifth category for the results of operations on the knee-joint in childhood, which too often are followed by many inches of shortening in adult life. In the first four of these categories the actual shortening due to defect of osseous tissue seldom exceeds two or three inches, but the effective shortening (often called "apparent," but which Professor Hey Groves prefers to call "functional") may amount to more than seven inches in cases of faulty ankylosis. If this disproportion in length were the only ill effect it would be serious enough, but unfortunately it is only by the production of serious distortions of the spine and pelvis that contact between the sole of the foot and the ground can be effected when the knee is extended in such a case. The minimum ideal at which orthopaedic surgeons of to-day aim is such an end-result in all cases of infectious hip-joint disease that the shortening, if any, shall be only that caused by inevitable destruction of bone; that the femur shall not be adducted, but rather, if fixed, then fixed in slight abduction; and that flexion deformity shall be absent. The maximum ideal, rarely achieved as yet, but still always held in view, is a complete restoration of all the functions of the joint without alteration in length. When these ideals are realized the work of the bone and joint surgeon and the sufferings of patients will be much diminished. But surgical tuberculosis may be eliminated before that comes to pass.

It will be noted that Professor Hey Groves deprecates the practice of producing a factitious temporary talipes equinus as a means of compensation for a short limb; at most he would admit a raising of the heel so as to produce plantar flexion of the ankle of fifteen degrees beyond the right angle. The disadvantages of digitigrade gait are indeed, as he argues, demonstrable, but something must be allowed for aesthetic considerations. Many a woman would prefer—and does prefer—to walk awkwardly with a factitious talipes equinus of 45 degrees beyond the right angle, with all its disadvantages, if by so doing she can escape the clumsy high cork of the usual surgical high-boot. Two-inch heels placed far forward under the soles of shoes, and thus further exaggerated in effect, seem to be deliberately chosen by many thousands of women who suffer from no inequality of the limbs, and who would not admit that they suffer from any disturbance of the muscular balance of the leg as a result of what from anatomical and physiological points of view are preposterously absurd shoes. Many of them, as years pass, will have to pay the price of pride, in the pain which as yet they do not feel, but they are not open to arguments based on anatomical and physiological principles.

SURGICAL RESEARCH

The annual report of the Conservator of the Museum of the Royal College of Surgeons of England contains matter of unusual interest. It is no secret that Sir Arthur Keith has long aspired to see the College take the lead in advancing the knowledge on which the practice of surgery is based. That he has not been content to rest on the mere aspiration is abundantly

evident in the present report. Last year saw the first step in the project in the shape of an installation of laboratories, and the provision, with the help of generous friends of the College, of several scholarships. During the current year the scheme which the Council has taken in hand may be said to have advanced by leaps and bounds. The next step was to provide research workers with a fully equipped biological station where animals could be maintained in the best conditions—that is to say, in the country. The accomplishment of this costly project seemed to be remote, when a benefactor appeared with the offer of a gift which Sir Arthur Keith rightly describes as the most beneficent that any surgeon has ever made for the advancement of his own profession. Mr. George Buckston Browne, F.R.C.S., on learning of the scheme, expressed his sympathy with the movement, and offered to convey to the College a sum sufficient to cover the building, equipment, and endowment of a station such as the Council had in contemplation. To that end he most generously offered to give £50,000 at once, with a promise that the gift should ultimately reach the sum of £100,000.

It will be remembered that Mr. Buckston Browne purchased Darwin's house and estate at Downe, restored and endowed them, and handed them over as a gift to the nation. Thanks to his further liberality thirteen acres adjoining the Downe property have now been purchased, and the foundation stone of the new biological station to be built thereon and called the Buckston Browne Surgical Research Farm, will be laid by the President, Lord Moynihan, on Wednesday, July 8th, at 4 p.m. The building will include suitable animal houses, experimental laboratories, and operating theatres, and a residential block for the accommodation of research workers and the official staff. The social aspect of the scheme has been insisted on by Mr. Buckston Browne, and comfortable residential quarters are to be provided with that end in view. It is stated that the institution is to be staffed, not by men who take up research as a profession, but by those who have devoted or propose to devote their lives to surgery, and desire to elucidate particular aspects of their work by animal experiments. To secure unity of effort the supervision of the work carried on at the College and at the research farm will be entrusted to the Conservator of the Museum. The scholarships at present available were referred to in last year's report; for the completion and ultimate success of the scheme a capital sum is required which will provide an annual income of £2,500 for scholarships.

Little space remains in which to mention the activities of the various departments of the Museum during the past year, but visitors will have the opportunity of inspecting the additions, which will be on view in Room 1 from July 2nd to 25th. Among these medical men will be more especially interested in the numerous additions to the pathological section, many of which are singled out in the report of the pathological curator, Mr. Cecil Beadles, F.R.C.S., as being of unusual interest.

GEOGRAPHICAL DISTRIBUTION OF DEATHS FROM CANCER IN ENGLAND AND WALES

In the current number of the *Annals of Eugenics* Dr. Percy Stocks and Miss M. N. Karn make a valuable contribution to the study of the regional distribution of cancer.[1] The data used by them were the deaths at ages in the two sexes from cancer (all sites) and from tuberculosis during the period 1921–26 in the counties of England and Wales. The rates of mortality were carefully standardized, allowance being made for differences of age distribution *within* each quinquennial age group, and also for varying proportions of urbanization in the county groups. It follows that the large differences in rates of mortality which are shown on the well-executed maps—for instance, the high rate on males in a north-western nucleus, which includes Cumberland and most of North Wales—are not due to simple statistical differences in the nature of the populations exposed to risk. The authors then seek, by means of the calculus of correlation, to determine how far inter-local contrasts are explicable by local variations of diagnosis, and how far other, more fundamental, causes are in operation. They conclude that, although varying efficiency of diagnosis, certification, and treatment plays a part, it certainly does not account for the whole of the diversity. "In order," they say, "to account for the bulk of the local and regional correlations between cancer rates, it must be assumed that there are factors at work tending to cause cancer deaths at earlier ages in certain localities or regions than others. The nature of these remains obscure." This memoir, which confirms and considerably extends the results published by Greenwood and others in the League of Nations Report,[2] should encourage statisticians to give further attention to the subject. The statistics of cancer are beset with so many pitfalls that few statisticians care to tackle them. Dr. Stocks and Miss Karn show that, difficult as it may be to reach clear-cut etiological conclusions, accurate statistical analysis may yet lead to results of real importance.

SCHISTOSOMA SPINDALE

Serological investigations into parasitic infections of man and animals have produced only three outstanding diagnostic tests—for dourine in horses, and for hydatid and bilharzia disease in man. Others, including tests for trichinosis, are under investigation, but so far none have reached a stage suitable for general diagnosis. This does not mean, of course, that the diagnosis of parasitic infections is more difficult than that of bacterial infections; alternative methods are more satisfactory in many cases—blood smears, faecal examinations, and so on are applicable to many. Nor does it mean that investigations on the host reactions of parasites have not been extensively carried out. It is true that there are fewer parasitologists than there are bacteriologists, and consequently the volume of work must necessarily be smaller. It is true, also, that animals are less amenable to laboratory experimentation than are plants, and so progress is necessarily slower. Nevertheless, a considerable volume of work has accumulated. Much of this has been in the domain of comparative pathology, an instrument which has always been of the greatest use in this branch of medicine. The latest publication on

[1] *Annals of Eugenics*, vol. iv, Parts III and IV, May, 1931, p. 341.
[2] Société des Nations. C.H. 333. Geneva, 1925.

comparative parasitology bears out this contention. It is a study on *Schistosoma spindale*, a bilharzial parasite of the buffalo and goat in India, by Dr. N. Hamilton Fairley, Colonel Mackie, and Dr. Jasudasan.[1] Like *S. mansoni*, this species lives dominantly in the portal and mesenteric veins, with ova deposition in the entero-colon and liver. The liver, in both cases, bears the brunt of the portal toxaemia, and filters off the circulating ova and toxins from the mesenteric veins, causing a bilharzia cirrhosis, and, perhaps, a tendency for the production of hepatic carcinoma so often associated with the disease. In *S. haematobium*, on the other hand, the adults inhabit the pelvic plexuses of veins, with ova deposition in the bladder and ureters, while the lungs, owing to the venous connexions of the pelvic plexuses, are implicated instead of the liver. In *S. mansoni*, verminous thrombosis is rare; in *S. spindale* it is by no means uncommon. The ova in this species are less toxic than those of *S. mansoni*, and lesions in the intestine are therefore less marked. The human schistosomes will easily infect monkeys; not so the bovine species. The parasite begins to develop in the monkey, but either because of some obscure anti-schistosomal immunity response, or because of some inherent unsuitability of the blood, development is arrested after ten days, and the parasite dies. Apparently after this recovery there exists a condition of enhanced refractiveness, during which the schistosomes entirely fail to develop; but within three months the normal partial susceptibility is re-established. The biological tests for the schistosomes are group tests, and any species of mollusc which harbours mammalian bilharzia cercaria may be used for antigen manufacture. In India 20 per 1,000 snails were found to be infected, compared with 180 per 1,000 in Egypt; and the best time for collection was found to be during the cold season in both countries. The authors have elaborated a standard diagnostic technique with this antigen and complement fixation, which gives a high percentage of positive results with goats. The test promises to become of importance in clinical pathology.

DURATION OF LABOUR

An investigation is being conducted in Finland with a view to determining the duration of labour in normal primiparae and secundiparae, and to define the effect of a preceding abortion, or premature labour, on the length of subsequent labours. The first part of the report[2] on these subjects has been compiled by Dr. A. M. Ritala, and is published as a Supplement to vol. xi of the *Acta Obstetricia et Gynecologica Scandinavica*. This deals solely with the duration of normal or second labours in women between the ages of 20 and 24. The duration of the first and second labours of the same woman was observed in 513 cases. An equal number (1,718) of cases of first and second labours make up the material on which the report is founded; in all of them the conditions were normal. Ritala has come to the conclusion that the previously recorded studies on the duration of labour are incomplete, and that the information contained in obstetrical textbooks is so inaccurate and defective as to be misleading; he enters into a long statistical argument in illustration of this contention. Among his more important findings is the fact that some difference was clearly noticeable in the duration of labour in different parts of Finland. Thus, in hospitals in the west and south of that country labour was definitely shorter than in the east and north. National idiosyncrasy was also apparent, the duration in Russian women being generally shorter in all stages than in the case of Finnish women. Again, at the Helsinki Maternity Hospital the length of the second stage of labour is significantly less than it was forty years ago. Ritala laments that no reliable comparison could be made with other countries in view of the fact that the standard error of the arithmetic mean has not generally been calculated when compiling statistical records. He suggests, with a view to clearing up the situation, that much more careful statistical standardization is necessary in the first place. Moreover, the material used for such study should be as homogeneous as possible. He recommends, for example, that as regards duration of the first stage, the cases should be classified on the basis of frequency of pains at the beginning of labour—what he terms "regular" cases (with a ten minutes' interval between the pains as the limit) being distinguished from "irregular" cases. He suggests, also, that the time of the active expulsive pains should be described in records of the duration of labour as the second stage. He could find no ground for prophesying with certainty the length of a subsequent labour on the basis of the duration of a previous one. His results point, however, to the conclusion that a first full-length labour, following an abortion between the first and seventh months, will have the characteristics of a primiparous labour, being longer than in the case of the two-para. On the other hand, a first full-length labour which ensues after a premature labour, terminating between the eighth and the tenth month, will have the general characteristics of a two-para labour.

THE TRUDEAU SANATORIUM

In November, 1876, Dr. E. L. Trudeau, with a growing family and his strength sapped by tuberculosis, removed to the then tiny village of Saranac Lake. Gradually winning back his health, he set himself to provide accommodation and assistance for fellow sufferers whose means were inadequate to sustain the whole cost of the long treatment. In 1884 he founded for them the sanatorium which bears his name, and this has been followed by a group of other buildings round it. A training centre for nurses was opened in 1912, and four years later an endowment fund, the Trudeau Foundation, was established to foster research into the problems of tuberculosis, and to promote the giving of instruction. There has just been issued the forty-sixth report of this great and growing organization, which now comprises a sanatorium of 185 beds, a training school for nurses, a post-graduate institution, a system of research fellowships, two laboratories, and a department for statistical investigations. It is announced that during the year ending September 30th, 1930, a record number of patients (525) were treated, and 336 were discharged.

[1] *Indian Medical Research Memoirs: Studies in Schistosoma spindale* Parts i–vi. By N. Hamilton Fairley, M.D., D.Sc., F.R.C.P., Colonel F. P. Mackie, M.D., M.Sc., D.P.H., F.R.C.S., F.R.C.P., I.M.S., and F. Jasudasan, L.M. and S. Calcutta: Thacker, Spink and Co. 1930.

[2] *Studien uber die Geburtsdauer in Finnland.* Von A. M. Ritala. *Acta Obstetricia et Gynecologica Scandinavica* vol. xi, Supplementum I. Helsingiae: Typis Espressit "Mercator." 1931. (Marc. Fenn 80; Coron. Suec. 8.)

A new nurses' home was completed, and opened. Printed together with the report is the twenty-sixth medical supplement, giving clinical details and a condensed record of those patients who have been discharged during the year under review. Under the present system all cases with cavities are radiographed every six weeks; if continued improvement with contraction of the cavities is not observable within three months, the advisability of performing pneumothorax is seriously considered. If this operation fails, phrenicectomy becomes a probability. It appears that 25 per cent. of the smaller cavities disappear under enforced rest, when occurring in connexion with tuberculosis of recent origin, as is the case in the majority of patients admitted to the sanatorium. In the laboratory attention is being directed to the biological study of the tubercle bacillus; three non-pathogenic acid-fast organisms have been "dissociated," and as the result of their cultivation on spinal media it has been shown that the subsequent development of pathogenicity in them depends to a large extent on the medium used and its gaseous environment. The chief difficulty encountered has been the stabilization of the various types of colonies obtained by dissociation. The annual report concludes with reprints of twelve papers by members of the Trudeau Foundation which had previously appeared in medical periodicals. The May issue of the *Journal of the Outdoor Life*, a monthly magazine published by the National Tuberculosis Association of America, is devoted almost entirely to the many lines of activity at Saranac Lake. It contains a reprinted lecture by the late Dr. E. L. Trudeau, describing the history of his great achievement. Illustrations are provided generously to indicate the various improvements that have been made during the last fifty years, and the usual reference appears to Robert Louis Stevenson's residence in the village in 1889.

LADY OSLER

With a skilful touch Mr. Arnold Muirhead tells the story of Grace Revere Osler's life[1] from the happy days of youth with her charm and loveliness, natural dignity, and withal love of healthy fun, to the dark days of the war, followed by her brave widowhood and death on August 31st, 1928. Born in 1854 of an old Boston family of Huguenot extraction, she married, in December, 1876, Samuel W. Gross (1837–1889), the able son and successor of S. D. Gross, "the emperor of American surgery" of Philadelphia. Her acquaintance with Osler, begun in the city of brotherly love, culminated in a traditional unconventional proposal on the day Osler's first edition of his *Medicine* was published; he is said to have called on Mrs. Gross, then staying with mutual friends in Baltimore, and to have said with reference to a big red book under his arm, "There, take the darn thing! Now what are you going to do with the man?" How she cared for him, shielded him, and enabled him to devote all his energies to his life's work in the bright days at Baltimore, and at Oxford until the war, is pleasantly sketched. Then the clouds began to gather: anxiety for their only son and his death at the front, her double bereavement, and her courageous life in the house while the famous library was being prepared for its home in McGill University, Montreal. The first boxes for the transmission of the books arrived two days before her death, so she was spared the sight of the emptied rooms, which, though she had furthered in every way possible, she dreaded. "With her passing many felt that a chapter in their lives and in the life of Oxford had ended." This affectionate tribute recalls the influence of a husband and wife who in two continents had the love and admiration of the medical profession in a degree never equalled and unlikely to be surpassed in the future.

NEW YORK POST-GRADUATE MEDICAL SCHOOL

In accordance with the agreement between the New York Post-Graduate Medical School and Hospital and Columbia University, by which the former now becomes the post-graduate school of medicine of Columbia (see *British Medical Journal*, February 28th, 1931, p. 363), Dr. Nicholas Murray Butler, president of Columbia University, has set up an administrative board of post-graduate studies in medicine, on which members of the governing body of the university, the undergraduate medical school, and the post-graduate school of medicine are represented. Under the terms of the affiliation this board will have general oversight and control of all post-graduate instruction in medicine offered by the university, whether at the medical centre, the post-graduate medical school, or elsewhere in the city. The trustees of Columbia University have appointed Dr. Edward H. Hume as director, and Dr. Alan R. Anderson as associate director of the post-graduate school. This incorporation of the New York Post-Graduate Medical School into the teaching system of Columbia University as its post-graduate school of medicine, distinct from the undergraduate school, fulfils, after some forty-nine years, the ambition of those who resigned from the Faculty of the New York University upon the refusal of the trustees to grant them a separate building for post-graduate instruction, and organized early in 1882 the post-graduate school and hospital. Dr. D. B. St. John Roosa, the leader of this small group of pioneers, and first president of the institution he helped to found, pointed out in his inaugural address that while organized temporarily as an independent undertaking, this type of medical education ought to take its place among other forms of professional instruction within a university. "The time will come," he said, "when this institution will be included within a great university." His prophecy was fulfilled on July 1st, 1931.

BRITISH MOSQUITO CONTROL INSTITUTE

Apart from their fundamental importance as vectors of various kinds of tropical disease, mosquitos sometimes render life almost intolerable; and in this respect their activities extend from the Equator to the Arctic Circle. It is accordingly gratifying to note that the institute established at Hayling Island in 1920 is more active than ever, as the report submitted by the director to the annual meeting in December, 1930, shows. The mosquito control work was initiated in 1920, but the present institute was not built until 1925. It has many branches of activity. It supplies advice relating to mosquitos and their control, both by visits and by

correspondence, and applications for this advice continue to increase. It collects and identifies mosquitos sent in, conducts experiments on various methods of control, provides hospitality for visiting entomologists, and so on. It also performs important educational functions by providing short courses of instruction, maintains a teaching museum and a library, prepares instructional diagrams and photographs, and, in the person of its energetic director, Mr. J. F. Marshall, gives lectures and demonstrations at various meetings. The institute is doing useful and serviceable work in preserving the health and the comfort of the community; it receives no funds from official sources, and has a quite inadequate income. Scientific bodies as well as individuals may become members for an annual subscription of a guinea.

We greatly regret to announce the death of Mr. E. B. Turner, F.R.C.S., the senior member of Council of the British Medical Association, whose work for the profession and the Association, as Chairman of the Representative Body and in many other capacities, had earned the gratitude of all members. An obituary notice will appear in our next issue.

ST. MARY'S HOSPITAL

NEW MEDICAL SCHOOL AND PATHOLOGICAL INSTITUTE

The foundation stones of the new medical school and pathological institute buildings attached to St. Mary's Hospital were laid by H.R.H. The DUCHESS OF YORK on June 30th. This is the first stage of a great scheme of rebuilding to which the hospital has set its hand. It is hoped before long to begin building a new nurses' home on an adjoining site, to provide accommodation for 500 nurses, and to set free existing buildings, which will be used for providing beds for paying patients. By the transference of the inoculation department to new premises, also, thirty additional beds will be available, which it is proposed to use as maternity beds. When the scheme of rebuilding is complete it is claimed for the hospital that it will have a range of modern buildings comparing favourably with any hospital in London. The school of medicine and the inoculation department will constitute a roughly triangular block to the east of the main hospital, with frontages to Praed Street, Cambridge Place, and South Wharf Road. They are being built to the designs of Sir Edwin Cooper, and will be five-storied buildings, of striking appearance, and surrounding a dignified quadrangle. Old-fashioned and inadequate accommodation has hitherto hampered the work of the Medical School, which has outgrown its present premises. The new development has been made possible by some outstanding donations, including £63,000 from Lord Beaverbrook and £25,000 from the late Lord Revelstoke. For the inoculation department also it was very necessary to obtain a permanent and more commodious building, to which the Earl of Iveagh has generously contributed £40,000. It was stated, however, that no less a sum than £300,000 is required to complete the developments and extensions.

The Duchess of York was received on arrival by Lieut.-Colonel H. E. Verey, chairman of the hospital, Dr. C. M. Wilson, dean of the Medical School, Sir Almroth Wright, principal of the Institute of Pathology and Therapeutic Research, and the architect. After members of the board of management and the medical staff had been presented, Colonel VEREY gave an address of welcome, in which he referred to the association with the Royal House which St. Mary's had enjoyed since 1845, when the Prince Consort laid a foundation stone of the hospital. The Duchess, with a mallet formerly used by Queen Victoria, then laid the stones, first of the medical school, and then of the pathological institute, and a prayer of dedication was offered by the BISHOP OF KENSINGTON.

MR. BALDWIN ON ENDOWMENT OF MEDICAL EDUCATION

The Right Hon. STANLEY BALDWIN, M.P., delivered a brief address. He said that many laymen failed to realize that it was barely a quarter of a century since the medical schools of this country were dependent on the students' fees for their very existence. Now they derived a portion of their income from grants, but for many years to come the building of medical schools, and largely the running of them, as well as provision for research, would depend to a great extent upon the gifts of the public. With all the generosity they showed to hospitals, the public were unaccustomed to give money for the purpose of medical education and for scientific research. Yet the training of future generations of medical men and women rested with the schools, and upon what was done in those schools depended the standard of accomplishment in medical practice. Mr. Baldwin instanced the insufficient facilities in London for the training of medical students in obstetrics. It was true that the London County Council was contemplating the addition of obstetric beds to municipal hospitals, but such hospitals had no schools. If it was possible to give extra facilities in any kind of hospital, these ought to be given preeminently to hospitals which trained students. The new developments at St. Mary's, Mr. Baldwin continued, had been made possible by the generosity of a few men of vision, but it was necessary to secure the interest of the general public in the functions which hospitals discharged in respect to medical education, no less than in their more obvious task of aiding the sick and injured. He referred to the great work done by Sir Almroth Wright, whose department would now have a new and more worthy home. He described Sir Almroth as being in the apostolical succession of Jenner, but he was sure that he would be the last to deny that there were potential Almroth Wrights in the raw material from which medicine was drawing its future practitioners, and it was to discover and encourage that talent that an appeal was made for the endowment of research. The medical profession made a stern demand on its pupils; for seven years a man must maintain himself, or be maintained by his family—a great thing to ask in these days. Exceptional men did not come from any particular class of the community, and one way of obtaining them was by means of medical and research scholarships.

Dr. C. M. WILSON, dean of the Medical School, in proposing a vote of thanks to the Duchess of York and to Mr. Baldwin, said that the hospital was indebted, not only to the donors mentioned, but also to the authorities of London University for a liberal grant and for a spirit of understanding, which made it a pleasure to work with them. The new buildings would be valued, not only for the material advantages they supplied, but because the spirit of service in an institution was fostered by a beautiful environment. The fame and fortune of a school were not in bricks and mortar, but in the traditions which were absorbed by its students. Sir ALMROTH WRIGHT, in seconding the vote of thanks, paid a tribute to all who had worked with him during the last thirty years. After the ceremony the operating suites, wards, and laboratories of the hospital were inspected by the very large company who attended.

THE DIPHTHERIA DISASTER AT MEDELLIN

[FROM A CORRESPONDENT]

In the medical field as elsewhere we learn much from each other's errors; it is of importance that the full history of all accidents in medicine should be available. The publication is therefore to be welcomed of the full and frank details of the mistake which at Medellin, in the State of Colombia, South America, led to the deaths of sixteen children.[1]

Diphtheria of a virulent type had been present in the district. In 1928, 45 of 105 patients died; in 1929, 68 of 109; and in 1930, 30 of 271. In consequence it was decided to test children by the Schick method and to immunize them with formalinized diphtheria toxin—that is, formol-toxoid (Ramon's "anatoxine," also called "vaccin antidiphtérique"). A number of children were tested, and all went well until the immunization of a group of children at Las Salas Cunas.

On October 7th, 1930, forty-eight children, mostly between the ages of 2 and 7, all of whom had given a positive Schick reaction, received their first injection. Formol-toxoid prepared locally was used, and all injections were made subcutaneously into the scapular region. The first injection of 0.5 c.cm. was given on October 7th; seventeen days later 1 c.cm. was given, and three weeks later, on November 14th, a third injection of 1.5 c.cm. For this third injection a bottle of toxin was used in error instead of formol-toxoid. Its minimum lethal dose was, when freshly prepared, 0.002 c.cm. At the time it was injected into the children the m.l.d. was found to be 0.004 c.cm., the children thus receiving about three hundred and seventy-five times the amount of toxin that would kill a guinea-pig.

From accounts subsequently collected, it appears that many of the children were seriously ill during the night—that is, within some twelve hours of the injection, which had been given about 2 p.m. The first alarming accounts reached the doctors concerned on the afternoon of November 15th, about twenty-four hours after the injection, when one child died during the afternoon. Antitoxin was then collected, and a party of doctors set out through the town to visit all the forty-eight children in their homes. The difficulties were great, for the addresses of many of them were not known. Between 5 and 7 o'clock that afternoon about fifteen children were traced and all given between 8,000 and 12,000 units of antitoxin. Unfortunately it was not found possible in the existing confusion to give serum intravenously, as, Dr. Ramirez remarks, he would naturally like to have done.

During that night three children died. Next day more were traced, serum was given, and as many children as possible sent to hospital. The first death occurred about twenty-four hours after the injection; within sixty hours of the injection fourteen children had died. Six days later one more died, and six weeks later one died of post-diphtheritic paralysis—thus sixteen of the forty-eight children injected succumbed.

CLINICAL COURSE

The general picture was one of toxaemia. The accounts subsequently got from the parents showed that during the first night after the injection the children suffered from pain at the site of injection, with fever, and with restlessness often going on to convulsions; some reported vomiting, and a few diarrhoea.

In the report the children fall into four groups. In the first group (A) of twenty-six children, some were ill during the first night; the majority received serum, and all were reported as well when discharged from observation during the first week in December. In the second group (B), consisting of three children, there was severe pain at the site of injection with much swelling, ulceration, and necrosis. All recovered after prolonged treatment. In the third group (C) of three children there was severe local pain, and post-diphtheritic paralysis; but all finally recovered. A photograph in the report gives an impression of the gravity of the local condition, with ulceration of the whole length of the back of the upper arm and contraction after healing. All the sixteen children in Group D died. In this last group high temperature, delirium, vomiting, and severe pain at the site of injection occurred. One child discharged well, and admitted a month later to hospital suffering from paralysis which had already been present for several days, was given no less than 290,000 units of antitoxin after readmission, but died of heart failure. Apparently few necropsies were permitted. The liver and kidneys were recorded as slightly engorged, and cerebral membranes were intensely congested. Microscopically the liver, kidney, spleen, and suprarenal capsules showed "cellular lysis" at different stages, with some haemorrhage.

It is striking that false membrane in the throat, apparently typical in character, was reported in ten children, smears and cultures were made but no diphtheria bacilli were found. It was not known how early this membrane appeared, but it was first detected forty-eight hours after the injection. Dr. Ramirez discusses this extraordinary phenomenon at some length, and is quite convinced that the membrane is produced by the circulating toxin, and is not, as we have hitherto believed, the result of the growth of the diphtheria bacilli on the tonsils and pharynx. Submaxillary adenitis was recorded in a number of children, presumably as a secondary result of the membrane and dirty tongue which were noted in many instances.

The escape of the thirty-two children in Groups A, B, and C, notwithstanding the injection of the large amount of toxin, is discussed at some length. Formol-toxoid (0.5 c.cm.) was injected thirty-eight days before the toxin, and 1 c.cm. twenty-one days before; though the formol-toxoid used was presumably of rather low antigenic power, it is in accord with much laboratory and clinical evidence that this amount of toxoid would have already begun to produce a material degree of immunity. The probability is that when the toxin was injected on November 14th, the children in Group A were already Schick-negative, those in Group B, who suffered severe local reaction, had a lower degree of immunity, those in Group C still less, while those in Group D had little or none—at all events, not sufficient to enable them to withstand the terrible ordeal represented by an injection of 300 guinea-pig m.l.d.

There is no conclusive evidence in the report that the serum used saved any of the children; quantities up to 80,000 units were given to children in the three groups which recovered, but even the first small doses were not given until clinical symptoms had been present for perhaps sixteen to eighteen hours, and the serum was given subcutaneously.

It is of interest to compare the clinical picture presented in the Bundaberg disaster with that recorded on other occasions when toxin has been erroneously injected—that is, at Baden, Concord, Dallas, and Medellin. At Baden[2] a dose of about 10 guinea-pig m.l.d. was injected and proved fatal in four days to children about a month old; the first local swelling appeared about twenty-four hours after the injection. At Concord[3] a sublethal dose of toxin was injected, for though some children had paralysis, none died. Within twenty-four hours "a severe local inflammatory reaction" was produced. At Dallas[4] a fatal dose of toxin was injected, and the local pain commenced within a few hours of the injection. The

children in Group D at Medellin, as we have seen, suffered severe pain during the first night. Among the Bundaberg children (whose deaths are attributed by the Australian Royal Commission to the staphylococci injected with the contaminated prophylactic) the general picture was one of collapse with cyanosis ; severe vomiting and diarrhoea were present in all, but local pain within a day or two of the injection is not recorded in any instance. This non-occurrence of local pain would appear to lend strong confirmation to the finding of the commission.

A further deduction is that, if it ever happens in the future that a group of children who are undergoing immunization complain of severe pain locally within a few hours of the injection, an instant examination of the material injected should be made, and consideration given to immediate intravenous injection of large doses of antitoxin.

In the laboratory at Medellin the bottle of toxin which was responsible for the deaths was kept in the same ice-chest with a similar bottle containing the toxoid used in the first two injections. The possibility of disastrous human error under such conditions is obvious. Surely no arrangement of the kind would be sanctioned by any of the inspectors who, under either the English or the American laws, grant licences to institutions producing serums and other like substances.

PREVENTION OF TUBERCULOSIS

CONFERENCE AT MARGATE

This year the conference of the National Association for Prevention of Tuberculosis, which was held at Margate from June 25th to 27th, elected to discuss one of the most important and comprehensive subjects that have ever appeared on its programme—namely, "The protection of the child from tuberculosis." A number of constructive issues were raised, and while it is not usual in such mixed lay and professional meetings to reach permanent conclusions, there appeared several very significant trends of thought.

After formal business, the vice-chairman of the council, Sir ROBERT PHILIP, delivered an introductory address which again revealed his power of defining the problem in its simplest terms. He assumed that tuberculous infection was contracted in childhood, and that its influence, for better or worse, remained throughout life. On the whole, this was a beneficial thing, but it was desirable to find out by means of the tuberculin test whether it had occurred. The avoidance of massive infection and of milk-borne disease was essential. His attitude to B.C.G. was one of caution. He pleaded for a closer liaison between the child welfare and tuberculosis departments of the public service. The address, although designedly not introducing any features of novelty, was an admirable prelude to the further discussions, and anticipated all the points that subsequently raised controversy.

Dr. EUGENE L. OPIE (Phipps Institute, Philadelphia) read a masterly paper on varying manifestations of the disease in childhood. He drew the accepted distinction between the disease of early infancy and that of adolescence—periods at which the greatest mortality occurred. The former was a primary invasion, the latter a second infection in a system partially protected. It was the latter that must be sought out in its latent stage, by a routine use of the tuberculin test and of stereoscopic films among the apparently healthy school population and those children in contact with open cases. The method of sputum examinations repeated at intervals was a very effective but neglected public health weapon. The actual number of school children with latent tuberculosis was very large, and there might be a long interval between the end of exposure and the onset of disease. Loss of weight was not a reliable sign. The diffuse opacity of infiltration was seen in the radiogram, with deeper shadows and perhaps partial calcification in the lymph nodes. The adult pulmonary type made its appearance about puberty, and was more serious than the childhood form. Used in conjunction with screening of the chest and the inspection of films, the tuberculin test gave useful information. Dr. Opie warned the conference that the large fall in the death rate revealed in statistics which included the aged, had tended to belittle the real extent of the problem in childhood and adolescence.

Dr. LETITIA FAIRFIELD surveyed the administrative side. The present death rate from tuberculosis in the age period 15 to 25 was practically the same as that of twenty years ago. For younger children, massive infection was the most important danger. The London County Council, for the last five years, had adopted the practice of boarding out children from families in which there was a sputum-positive case of tuberculosis. Continuous care of the tuberculous expectant mother must be developed further.

The remainder of the first day was occupied by a discussion of the milk problem, and this, as usual, proved to be one of the most controversial issues. Dr. NATHAN RAW gave an outline of the scientific position and the consequences of bovine infection. He described his method of immunizing calves by feeding with killed bacilli of an attenuated strain, cultivated by him for twenty-four years. As an immediate remedy, he advocated compulsory pasteurization. A more extreme position was taken by Dr. REGINALD JEWESBURY, who believed that ordinary commercial pasteurization could not be relied upon, and that even "Certified" milk, the highest grade, was not absolutely safe. The vitamin content of milk was uncertain ; orange juice and cod-liver oil should be added in every case.

The veterinary side of the case was very aptly put by Major D. S. RABAGLIATI, chief veterinary officer to the West Riding County Council, in a paper which does not lend itself to abstracting, but which should be consulted. He stressed the friendly character of the relations between veterinary surgeon and farmer in carrying out the Milk and Dairies Acts. In the general discussion, compulsory pasteurization made its usual facile appeal.

The second day of the conference dealt with the protection of the child during the years before school and in the school life itself.

Dr. T. R. ELLIOTT emphasized that children were the heirs of ignorance, and that infection must be prevented in the home. He had found boarding-out of children a difficult measure, but the segregation of the infant in a babies' home for the first twelve months was a practical possibility. After that age the protection devolved upon the health visitor. The chronic open case of phthisis, diagnosed or undiagnosed, was the chief danger.

Dr. NOEL BARDSWELL objected to the great difficulty of Opie's proposals for examining every school child with stereoscopic film and the tuberculin test. He believed that the person who developed tuberculosis in adolescence was not the one who was missed in school years. Sir HENRY GAUVAIN described the interplay of infection and resist-

ance. He was an advocate of pasteurization of the milk supply under proper control.

The more limited sphere of the school was considered in two excellent papers by Dr. RALPH CROWLEY and Dr. Midgley Turner. Dr. Crowley gave an inspiring summary of the newer ideals in humanizing education. Caution and conservatism did not pay. More residential open-air schools were needed, equipped with every kind of facilities for physical diagnosis. The term "pre-tubercular" was an inaccurate label. Without accepting one or other view of the cause of adolescent tuberculosis, Dr. Crowley favoured a much more intensive study of this condition, aided by every technical means at our disposal.

Dr. MIDGLEY TURNER referred to the danger of infection from school teachers. At present, although there were regulations governing the employment of a teacher once diagnosed as tuberculous, there was no provision for discovering new cases. He scouted the commonly held opinion that there was no pulmonary tuberculosis among children. They must not, at this period of life, look for initial infiltration, for the disease was confined to the root. Considerable institutional accommodation was necessary for children in this condition. Dr. L. S. T. BURRELL stressed that it was essential to have a reinfection before tuberculosis could develop in adult life. He believed that the tuberculous child rarely became the tuberculous adult; progress would be made by looking back from the adult case.

Views may differ on technical points, but it is certain that expert and lay opinion is now focused on the adolescent period as probably containing the key to adult phthisis. The result of the conference has been to bring the main problems into prominence in a much clearer manner than is the case at many gatherings of the kind.

EPSOM COLLEGE

ANNUAL GENERAL MEETING

The seventy-eighth annual general meeting of the Governors of Epsom College was held at the Royal College of Physicians on June 26th with Lord Burnham in the chair.

The following were declared to be the successful candidates in the recent election of pensioners, annuitants, and foundation scholars:

Pensionerships:

	Votes
*Marin, Mrs. Edith M.	3,523
†Shortridge, Mrs. Louisa...	3,467

* Hadlow Pensioner. † Ordinary Pensioner.

"Morgan" Annuity:

Waring, Miss S. Annette...	3,342

Foundation Scholarships:

Ring, Charles A. S.	12,436
Hyde, Edward K.	10,856
Parnell, James A. W.	10,672
Smith, Hugh F. S.	10,411
Evans, Raymond F. G....	9,614
Reid, Alexander P.	8,398
Walker, Robert G.	7,075
Armitage, Raymond S.	5,738

Mr. Frank Newcombe will be appointed an ordinary pensioner, under By-law 16, at the council meeting, which will be held on July 1st, 1931, a vacancy having arisen.

A by-law of the College which precluded a widow from sending her son to the College as a day-boy was amended so as to correct this anomaly.

At the termination of the annual general meeting an extraordinary general meeting of the Governors was held, at which the following resolutions were passed unanimously:

That the Council of Epsom College be and is hereby authorized to promote legislation to amend, extend, and repeal the provisions of the Royal Medical Benevolent College Act, 1855, and the Royal Medical Benevolent College Act, 1894, so far as may be requisite or convenient for the following purposes—that is to say:

1. To effect the abolition of the present method of election of Pensioners, Foundation Scholars, and Annuitants by the Governors of the College, and to substitute therefor election of Pensioners, Foundation Scholars, and Annuitants by a Committee to be appointed by the Council and to consist of twenty Governors, of whom ten shall be members of the Council and ten shall be Governors (not being members of the Council) whom the Council shall select annually as most adequately representing the varied interests of the Medical Profession.

2. To provide for the extension of the benefits of the charity so as:

(*a*) To enable Pensions to be provided for medical women (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as for medical men;

(*b*) To render the sons of medical women eligible for election as Foundation Scholars on the same conditions as the sons of medical men; and

(*c*) To enable Annuities or occasional pecuniary assistance to be provided for medical women or their families (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as such annuities and assistance may be provided for medical men or their families.

The council is taking steps forthwith to promote legislation in Parliament to make these resolutions effective. As this cannot be done before the early months of 1932, one more election on the old lines must necessarily be held in that year.

It will be seen that as a result of the proposed legislation the election of pensioners, annuitants, and foundation scholars will be in the hands of a composite committee, consisting, as to one half, of the council of the College, and, as to the other half, of governors selected annually by the council in such a way as to give to the medical profession in all parts of the country an important direct power in the election. Further, the benefits of the charity in future will be extended to medical women and their sons on the same terms as apply to medical men and their sons.

Scotland

Scottish Honorary Degrees

At the June graduation ceremony of St. Andrews University, held on June 26th, Principal Sir James Irvine, who presided, conferred the honorary degree of Doctor of Laws upon five recipients. These included one member of the medical profession—namely, Dr. George M. Robertson, professor of psychiatry in the University of Edinburgh. At the graduation ceremony held in Edinburgh University on July 2nd, the list of graduands who received the degree of Doctor of Laws consisted of eleven persons, including Sir George Andreas Berry, M.B., Member of Parliament for the Scottish Universities, and formerly lecturer in ophthalmology in the University of Edinburgh; also Sir Walter Morley Fletcher, M.D., F.R.S., secretary of the Medical Research Council.

Training the Deaf in Scotland

The annual meeting of the Edinburgh Royal Institution for the Education of Deaf and Dumb Children was held on June 24th, under the presidency of the Duke of Montrose. In commenting on the fact that this institution depended largely upon public charitable support, he said that while the deaf were not recognized by the State, blind persons might be said to be nursed by the Government throughout life. In his opinion deafness was the more grievous affliction. He referred to Helen Keller, who was

born deaf, dumb, and blind, and yet had been trained to take her part in the affairs of the world; she had considered that deafness was worse than blindness, and had given up her work for the blind in order that she might concentrate on work for the deaf. He was pleased to see the attention paid in the institution to lip-reading, but he did not agree with the statement that it should be substituted wholly for signs; in his view both forms of instruction should be given. He was glad to see that the children of the institution were encouraged to take part in all manner of sports, and were learning industries. He suggested that smallholdings for market-gardening, poultry-raising, and the like should be worked by deaf people in a group, with a hearing person to act as marketing agent.

At the hundred and tenth annual meeting of the Glasgow Society for Education of the Deaf and Dumb, held on the same day, Mr. Alan Burns, who presided, said that the directors were paying particular attention to vocational training. It was hoped that the society would be able to assist the Scottish Association for the Deaf in starting a shop for boot-mending by the deaf. After-care education, under a nurse as supervisor, formed an important part in the society's operations, and this had included 94 visits to ex-pupils, 413 general visits, and 178 visits to the sick.

The prize distribution of Langside School for the Deaf, Glasgow, was held on June 25th, under the chairmanship of Dr. Duncan MacGillivray, who said that it was being more generally realized that much of the labour expended on behalf of those who were handicapped in one direction or another was lost owing to the fact that they had not received a vocational training in their educational establishments. In London schools instruction was now given in cabinet-making, bakery, confectionery, and boot-making for boys, with laundry work and other occupations for girls. Mr. G. S. Haycock, superintendent of the school, said that evidence was accumulating that deafness in school children was decreasing, thanks to the improved school medical service of the country and to the better care now taken in hospitals of children suffering from scarlet fever and measles.

The annual meeting of the Scottish Association for the Deaf was held at Donaldson's Hospital, Edinburgh, on June 25th, with Dr. James Haig Ferguson, president of the Royal College of Surgeons of Edinburgh, as chairman. Dr. James Kerr said that a Royal Commission had been inquiring into the administration of Donaldson's Hospital and the Edinburgh Royal Institution for the Deaf, and an amalgamation of these two schools had been advised. It was imperative that all authorities, schools for the deaf, and the Scottish Education Department should unite for joint action in this matter. The association intended to appoint a legislative committee at once to draft a Bill similar to, but not identical with, the Blind Persons Act, with the object of providing work for the unemployed deaf. He pointed out that it was important that the training of the deaf child should begin as soon after birth as possible. Children began to talk normally in the second year, and if a healthy child was kept from speech till the middle of school life, it would probably be mute. This tragedy was happening too frequently in Scotland. There was need also for the association to urge education authorities to provide classes for "hard-of-hearing" children, who were from five to ten times as numerous as the completely deaf. The chairman remarked that there were about 40,000 deaf-born persons in the country who depended for subsistence upon voluntary agencies after the school age was passed. With regard to Donaldson's Hospital, the commissioners had proposed to make it a purely deaf-mute school, and to exclude altogether the hearing children whose presence had hitherto been an important feature of its existence. He doubted whether this was wise, and hoped that other counsels might still prevail, so that Donaldson's Hospital might go on caring for the best interests of both hearing and deaf children. The present inmates of the hospital included twenty-five normal children, of whom fifteen had both parents, and the other ten one parent, deaf and dumb.

Glasgow Dental Hospital

The annual meeting of the Incorporated Glasgow Dental Hospital, which is now nearing completion, was held on June 12th. The Earl of Home, who presided, remarked that this institution had existed for forty-six years, and had rendered invaluable services to the community. Improved facilities would be available in the new home of the hospital. Instead of thirty-five operating chairs there would be seventy, each of which would have a self-contained equipment including a supply of water, compressed air, gas, and electricity. There would be a separate department for children, and a special *x*-ray room, while the laboratory would provide ample accommodation for fifty students at a time. There would be three rooms available for research, and, for extractions, a large anaesthetic room and two recovery rooms. Dealing with the financial position, he said that the estimated cost of building and equipping the new hospital was £90,000, for which subscriptions amounting to £39,150 had been received. He appealed to the citizens to make it possible for the hospital to open free of debt. The dean of the hospital, Dr. J. Forbes Webster, pointed out that a grant for equipment of £2,000 by the Dental Board of the United Kingdom was contingent upon their raising £1,700 by July 1st; although that date was drawing near they were still about £400 short of the quota.

England and Wales

Guy's Hospital

The annual report on the work of Guy's Hospital for 1930 has just been issued. In his review the treasurer notes the continuous growth in the number of in-patients treated, which reached last year the total of 12,249 persons—between four and five hundred in excess of any previous figure. "This regular growth of the main function of the hospital—treating within its walls poor sick persons and restoring them to health—is the visible proof of skilful medical attention and studied organization. By the former the average stay of each patient in the hospital was reduced last year approximately from eighteen to seventeen and a half days, by the latter the average number of beds in daily occupation has been raised in twelve months from 553 to 563. Both factors widen the capacity of the hospital, and enhance the public value of the great charity founded two hundred years ago by the far-seeing benevolence of Thomas Guy." The total available number of beds in the hospital is now 648. Some 50,000 persons attending the out-patient department last year were interviewed by the inquiry officer, and of these about one per cent. were found to be able to pay for the treatment privately. "The fact that 40 per cent. of those interviewed bring, on their first visit, cards or letters of recommendation from their own private doctors shows to how great an extent the hospital has become the specialist and consultant of the poor." The new out-patient department is approaching completion, and will be opened in the latter half of this year. The total number of medical students in attendance during the year 1929-30 was 449, and besides these there were 301 students at the Dental School. Another passage in the treasurer's report will be read with interest by many who are not old students of

the school: "Every visitor to Guy's knows the statue of the Founder, Thomas Guy, occupying the centre of the front quadrangle. But it is not so well known that the statue, obviously a fine piece of work, is well-nigh unique among London statues, being of brass, by Scheymaker, an artist famous in the eighteenth century. By the expert advice kindly offered by H.M. Office of Works, the statue, which is in excellent condition, has been cleaned at a small cost."

L.C.C. Medical Officers: Study Leave and Outside Appointments

A regulation of the London County Council provides that leave of absence for a period not exceeding six weeks in any one year may be granted to an assistant medical officer desiring to undergo a course of medical instruction at a university, such leave to be on full pay in the case of officers with five years' service, on half pay in the case of officers with two years' service, and without pay in the case of officers with less than two years' service. It is now proposed by the Central Public Health Committee to amend the terms of the regulation so as to provide that leave may be granted not only to officers who are following university courses, but also to those who are undertaking other approved courses of study, or research work, or investigation in this or other countries, where it is deemed that such study will be of benefit to them as medical officers in the public health service of the Council, and of advantage to the Council's service itself. The committee has also recently had before it applications from two medical officers attached to council hospitals for permission to apply for honorary appointments on the staffs of voluntary hospitals. The committee expresses the view that, generally, the staff should be encouraged to hold such appointments, as association with outside medical work provides valuable experience which will be of benefit in carrying out their duties under the Council. In the case of the county mental hospitals there is already a rule that the medical superintendent may hold an appointment unconnected with his office—for example, physician to an out-patient clinic at a general hospital—on such conditions as the council may decide. The committee thinks that similar facilities should be granted to the medical staff in the hospital service generally if, as in the case of the applications just mentioned, the appointment is an honorary one, the holding of it will not in any way interfere with the efficient discharge of the officer's ordinary duties in the Council's service, and the work entailed by the appointment will be carried out in the officer's off-duty hours.

London Maternity Hospitals

In the annual medical report of the General Lying-in Hospital, York Road, Lambeth, it is stated that, during 1930, 1,165 women were delivered in their homes and 1,068 in the hospital. Of the hospital patients one died, and there was an infant mortality of 59 per 1,000; there were forty-one cases of albuminuria of pregnancy with no maternal deaths, and a foetal mortality of 12.19 per cent.; the maternal morbidity rate for the puerperium was 1.3 per cent., and only two Caesarean sections were performed during the year. In the clinical report for 1930 of the East End Maternity Hospital, Commercial Road, E., there is a brief account of the activities of this institution, since it opened as a "home" in Glamis Road, Shadwell, in 1884. During the first four and a half years 427 patients were admitted, and during 1930 the number was 1,450. There were no cases of eclampsia, and Caesarean section was not performed in the year under review; the maternal mortality rate was 1.38 per 1,000, and the infantile mortality rate 34.3 per 1,000. The attendances at the ante-natal clinic numbered 10,441.

Correspondence

DIVERTICULA OF THE COLON

SIR,—I regret that I did not see until this month the article upon diverticula of the colon and their sequelae by Mr. Lockhart-Mummery and Dr. Graham Hodgson in your issue of March 28th, or the just comments by Mr. Gilbert Scott and Dr. Muir on April 11th, as I was unable to see the *Journal* at those times. The paper is of much interest, and, whilst the authors' experience confirms in the main that of previous writers, there are four matters on which I should like, with your permission, to comment.

1. The authors say that they have, with Dr. Dukes, been able to show that the appearance of the prediverticular stage "is not due to inflammation, but is caused by very small and numerous diverticular 'buds' in the colonic wall"; in other words, that the term "prediverticular" for the appearance Mr. Marxer and I have described is a misnomer. The investigation by these distinguished observers, including a surgeon, is much to be welcomed, for, since early diverticulosis is not fatal, suitable material is hard to come by except at operations; and it is by such collaboration between the radiologist, histologist, and clinician that the early stages of diverticulosis need to be studied. I venture, however, to suggest that the evidence presented does not prove the conclusions drawn. The proof offered consists of a drawing of a microscopical section, published without description, of a piece of bowel showing the early formation of crevices and pouches; also radiograms of a bowel in different stages of diverticulosis. A small part of this bowel, so far as can be seen in the illustration, is in the prediverticular state; but much of it, like the section, appears to us to be in the second stage of forming diverticula, which Mr. Marxer and I have described as the aftermath of that state. Any histological evidence should be got from a section of the part of bowel previously identified by *x* rays as the exact area which was in the prediverticular state. It should also be confirmed by an *x*-ray, after incision, of the same area, the bowel having been hardened when distended. The authors do not show which piece of the bowel in the *x*-ray picture was removed for section, or make it certain that any of it was. For if Figs. 9 and 10, showing different stages of development of diverticula, are not of the same bowel, then the text is open to mislead; if they are, the specimen could hardly have been taken from that bowel at the first stage. We have obtained and have examined sections of areas accurately identified by *x* rays before and after removal. Reference has been made to these (*British Medical Journal*, 1929, ii, 570), and further reports will be published upon new material. We believe that we can often recognize a real prediverticular state. Similar observations have been made by other workers (see J. T. Case, *Amer. Journ. Roent.*, 1929, xxi, 207) and independently, unknown to us, by George and Leonard, pioneers in this field. The pathology of the prediverticular state is as yet unsettled, but I suggest that it deserves further consideration from my friends Mr. Lockhart-Mummery and Dr. Hodgson. The conclusion that multiple diverticula of the colon are pulsion pouches, pure and simple, and that there is no preceding pathological change other than senile weakness of the wall to determine where and when they arise, is that which most observers, including George and Leonard, and ourselves, assumed at first. But it does not explain the features revealed by a closer study. If the little herniae are due only to general causes—for example, a bowel thinned with age and internal pressure—the progress of the disease should be, as the years go on, roughly uniform in regard to the rate and the areas affected. This may be sometimes the case,

but we find that most often it is not. In the course of fourteen years' observation, particularly of the same cases seen year after year, we have noted that:

(*a*) Patches of the prediverticular state appear to creep about an affected bowel, with the subsequent formation of groups of pouches, all the same size, at that area. This may be quite close to an area of large pouches of some years' standing.

(*b*) Acute symptoms may occur at this stage. I have known a surgeon do a colostomy for an acute prediverticular state in a large area of sigmoid.

(*c*) The prediverticular appearance may be arrested in great part, and the irritation of that part of the bowel, and the symptoms, allayed by careful douching of the area and other measures formerly described.

(*d*) At the time of recurring attacks of an old (inflammatory) diverticulitis, new areas of the prediverticular state are often seen there or close by.

It is such clinical and pathological points, which are not considered in the paper by Mr. Lockhart-Mummery and Dr. Hodgson, that have led us to suggest that a mechanical cause, though no doubt a factor, is not the sole explanation of the way in which this disease arises and progresses.

2. The authors say that "diverticula can often be recognized by the barium meal method, but it is a very inexact one, and in this paper the radiographic appearances after the injection with a barium enema will be considered alone." We agree that the enema is most valuable, but have often obtained additional information when a barium meal has been given as well; for, particularly with a suspension, without cereal, of barium sulphate in buttermilk or malted milk, details such as tiny pouches are detected, which with the enema alone may be missed.

3. It is stated that the tendency to diverticulitis "appears to be definitely associated with a propensity to the deposit of excessive fat in the abdomen, and elsewhere." A comparison, published by us in 1927 (*Proc. Roy. Soc. Med.*, 1927, xx, 674), between 100 diverticulous and 900 non-diverticulous patients gave no evidence that diverticulous people in general are fatter than others of the same age. But the experience of Mr. Davies-Colley (*British Medical Journal*, 1926, i, 282), Mr. Lockhart-Mummery, and of other surgeons suggests that cases of diverticulitis in the later stages are more liable to need surgical help in the obese. This is probably because fatty tissue round an inflamed pouch is less vascular and therefore less able to resist an invading infection.

4. The authors speak of operations to prevent complications, and lay stress on the risk of perforation. This, in our series of 410 cases of diverticulosis, of whom the larger number sought relief for other complaints, appears to be about 1 per cent.; and, as there are thousands of people with quiescent diverticulosis who have not had symptoms leading them to be *x*-rayed, the risk in the general population is much less. Such a rupture is, of course, a disaster, though an operation within a few hours may yet save life; and the patient's medical man must always have the possibility of perforation in mind. It is natural to wish that this danger could be prevented by an operation. But the risk of a short-circuit, or excision, of a diverticulous area as a preventive of possible perforation in an otherwise healthy person is, even in the most skilled hands, many times greater than the risk to be avoided.—I am, etc.,

Ruthin Castle, June 20th. EDMUND SPRIGGS.

TREATMENT OF DYSMENORRHOEA

SIR,—Most gynaecologists are well aware of Dr. Sanderson Clow's invaluable contributions to the investigation and treatment of dysmenorrhoea, and one can only endorse the views she has expressed in her letter published in your current issue. Since she has implied, however, that gynaecologists are possessed of undue surgical enthusiasm in their efforts to improve upon nature, I must suggest that the primary responsibility lies elsewhere.

Private patients of this type are rarely referred to us nowadays; therefore we are possibly deprived of the opportunity of close study, as out-patient conditions are not ideal. But we do at least see dozens of cases under these conditions, such as they are; and my point is that the patients have almost invariably been told by their general practitioner that the trouble is due to cervical stenosis or a misplaced womb. On the other hand, he has all too frequently been good enough to guarantee a cure as a result of the dilatation of the cervix, which it is proposed that we should perform. Dr. Sanderson Clow will agree with me that it is difficult in these circumstances to persuade the patient to adopt less dramatic procedures, particularly as they impose the onus of treatment upon her rather than upon ourselves. As a result she usually gravitates sooner or later towards someone who is obliging enough to perform the operation originally recommended by her own doctor.

May I add that I have on two occasions performed, with apparent success, the operation of pelvic sympathectomy to which Dr. Venn Dunn referred in his address. But obviously it must be very rarely justifiable to perform a laparotomy with the object of treating dysmenorrhoea *per se*. Apart from the inevitable risk of an abdominal operation, the degree of genuine disability is always doubtful in these cases, as there are usually psychological factors. In one of my cases it was necessary to open the abdomen for other reasons, and in the second the patient was really desperate after all other measures had been given an extensive trial.—I am, etc.,

London, W.1, June 26th. FRANK COOK.

SIR,—Dr. Sanderson Clow's letter on the treatment of dysmenorrhoea raises some interesting points, and the bulk of opinion will be on her side in considering it unjustifiable to submit a large majority of patients to per vaginam examination under anaesthesia. She states that she has treated several hundred cases of dysmenorrhoea, in which gross pathological conditions were excluded, by means of daily exercises, with almost invariable cure. Dr. Clow rightly emphasizes a factor in the etiology of dysmenorrhoea which is of prime importance. As Professor Norman Miller and others have shown in late years, faulty posture and poor muscular tone play a large part in the production of menstrual pain, and further correction of these by suitable exercises produces remarkable results. Nevertheless, the claim of almost invariable success in several hundred cases is considerable, and one feels that in so important a subject it is not unreasonable to ask for definite figures, especially as the remedy is at once costless, simple, and at the ready disposal of the general practitioner. Dr. Clow has done a very valuable service in bringing forward this point, but the validity of the treatment would be better evaluated if actual figures were given.

I might add that I have been associated for some time with Dr. James Young, investigating cases of dysmenorrhoea in his clinic in the Royal Infirmary, Edinburgh. We have obtained very satisfactory results by organotherapy, especially by the administration of sistomensin. It is only very rarely that any of our cases have required dilatation of the cervix, and in this point also we are in agreement with Dr. Clow.—I am, etc.,

WALTER P. KENNEDY, Ph.D., L.R.C.P. and S.,
Edinburgh, June 29th. Beit Memorial Fellow.

CANCER OF THE CERVIX AFTER SUBTOTAL HYSTERECTOMY

SIR,—In the *Epitome* published with your issue of June 20th appears an abstract of a paper by R. Monod in *La Gynécologie* of February, 1931, in which it is stated that "Monod advises that the subtotal kind should be abandoned in favour of total hysterectomy." Monod has made a very important communication on cancer of the cervical stump, and I should be glad to welcome him as an advocate of total, to the exclusion of subtotal, hysterectomy; but, neither in the abstract in *La Gynécologie* nor in the full account in the *Bulletin de la Société Belge de Gynécologie et d'Obstétrique* (1930, p. 128), does he advise that subtotal hysterectomy should be abandoned. These are his words:

"Tout en restant fidèle a l'hystérectomie subtotale, soyons toujours prêts à pratiquer la totale et à en étendre les indications," and "sans aller jusqu'à conclure avec M. Herbert Spencer 'que l'hystérectomie subtotale est une opération que l'on ne doit plus faire,' la majorité des orateurs, partisans de la subtotale, admettent que dans de nombreux cas elle doit céder le pas à la totale."

I hope that gynaecologists will read the original paper of Monod and the discussion upon it—the *Bulletin* is in the Royal Society of Medicine's library—and be led to abandon the incomplete operation, as I did over thirty years ago (vide *British Medical Journal*, 1902, ii, 1131).—I am, etc.,

London, W.1, June 24th. HERBERT R. SPENCER.

ANAEMIC BREAKDOWNS CONNECTED WITH CONGENITAL HAEMOLYTIC JAUNDICE

SIR,—Among the many important points brought out in Lord Dawson's Hume Lectures (*British Medical Journal*, May 30th and June 6th) is the connexion of startling and dangerous "anaemic breakdowns," at various periods of life, with congenital haemolytic jaundice. In a woman, aged 34, under my care in hospital a year ago, who nearly died from anaemia, with ascites and pleuritic effusion, there was a history of severe anaemia, with enlargement of the spleen and jaundice, when she was 13 years of age. On examining her blood it was found that the fragility of the erythrocytes was excessive, haemolysis commencing when they were added to a 0.72 per cent. sodium chloride solution; her blood serum gave a strongly positive indirect (but negative direct) Hijmans van den Bergh reaction for blood bilirubin. Between the attack in childhood and the attack at 34 years of age there had been what were described as "bilious attacks without headache," which were evidently merely temporary exacerbations of icteric tinge connected with haemolytic jaundice.

She has relatively recovered, but at present still has a greatly enlarged spleen and moderate anaemia, and a variable sallow or slightly jaundiced face. I take it that in this woman an infection of some kind (with pleurisy, etc.) led to the second great "anaemic breakdown" in her life. Now comes the very serious question of recommending splenectomy in order to lessen her liability to another dangerous attack of anaemia and save her from the otherwise almost inevitable cholelithiasis (if she has not already latent cholelithiasis).

Not only is this patient not a true acquired case, as at first sight she had seemed to be, but probably she is not even really an "isolated" case. Though no family history of haemolytic jaundice can be elicited in her case, she is unlikely to be really the first case in the family, and I would point out that in the family series of congenital haemolytic jaundice cases described by the late Dr. G. Dorner and myself in 1910 (*Lancet*, 1910, i, 227, and *Folia Haematologica*, 1910, ix, 518) the father of the family was the only one out of fifteen children who inherited the jaundice from the grandfather, who had been jaundiced all his life, and died at the age of 76 years. A familial incidence can obviously easily escape recognition in the shifting population of London.

The present patient to whom I am referring has been only once pregnant, and the child was stillborn. With improved health following splenectomy more successful pregnancies may result, and the surgeon may enable the patient to bring forth a jaundiced generation for another generation of surgeons to deal with. I may add that the members of the haemolytic jaundice family about which I wrote with Dr. Dorner in 1910 have since furnished a striking example of "anaemic breakdown," and have given surgeons some work to do in splenectomy and cholelithiasis operations.

In regard to diagnosis, cases especially likely to give rise to difficulty are, I think, the anaemic ones, sometimes without obvious jaundice and with relatively little excess of erythrocyte fragility, especially if there happen to be likewise a suspicion of congenital syphilis in the family (cf. F. P. Weber, *Brit. Journ. Child. Dis.*, 1926, xxiii, 185).—I am, etc.,

London, W.1, June 28th. F. PARKES WEBER.

CONTACT GLASS OR CROSSED CYLINDERS

SIR,—I gladly welcome Mr. Beaumont's advocation of contact lenses in the *Journal* of June 20th, but I am not in favour of crossed cylinders in all cases. It is true that they are lighter than the equivalent sphero-cylinder, but in most cases of mixed astigmatism the glasses would be more periscopic if the concave spherical surface were placed next the eye.

In the case of L. T. with 18 D. of astigmatism almost certainly no benefit would be derived. I have not worked it out, but probably a crossed cylinder would give a far better result from a periscopic point of view if the minus cylinder were placed next the eye. With crossed cylinders +8 D. at 10 degrees and −10.5 D. at 100 degrees the vision was brought up to J. 1, and 6/9 for distance, but associated with a great deal of distortion.

There may be three reasons to account for this: (1) the *effectivity* of a crossed cylinder, or, indeed, of any lens of this power, will be greater when viewing objects at a distance than when reading at 30 cm. from the glasses. A +7.36 D. cyl. crossed with a −9.55 D. cyl. when used for distance will correct the same defect of the eye as a +8 D. cyl. crossed with a −10.5 D. cyl. when used for reading (see *Prescriptions of Spectacles*, p. 189). (2) Owing to the strands of adhesion described there would be some rotation of the eye (cyclophoria) induced by the act of convergence, so that the axes of astigmatism would be altered when reading and when seeing distant objects. (3) The pupil will be smaller when reading than when there is no accommodation exercised.

For reasons (1) and (2) a contact lens is the only conceivable single lens that would serve for distance and for reading.—I am, etc.,

Woking, June 29th. A. S. PERCIVAL.

CATHETER LIFE

SIR,—During the last forty years I have seen from time to time an old hospital patient. The following is a brief history of his case, given in his own words:

"On May 31st, 1891, being then 16 years of age and in perfect health, I went to the Whitworth swimming baths, Manchester. After diving in the water I felt a burning pain at my chest; the pain gradually became worse, and eventually very severe; then it suddenly left me, but at the same

time I lost partial use of my left leg, and in a lesser degree lost some power from my right leg. With assistance I managed to walk out of the baths, but I felt the use in my legs to be slowly leaving me; after walking about 300 yards I was obliged to sit down, and I then lost all power in both legs and became completely paralysed, and lost all sensation from the third rib downwards. I also lost all control over my bowels and bladder. From the time I dived in the water to being completely paralysed was about twenty minutes. I passed blood in the urine for several weeks.

"I was admitted to the Royal Infirmary in a completely paralysed condition; my bladder was greatly distended. I was in the Infirmary eight months, and for some time my bladder was washed out thrice daily.

"Eighteen months after the accident I managed to stand up, and then got to walk just a little with the aid of two sticks. For many years this condition prevailed. I could walk just a little, and my general health was good. (I washed the bladder out every day.)

"My present condition is: my back and legs are weaker than they used to be, and I get a lot of pains across the front of my head and left temple. As the urine accumulates in my bladder the pains in my head become more severe. At the same time there are many days when I feel very well indeed, and I am still able to carry on my business, but it certainly gets harder to do so.

"I have washed my bladder out every day for forty years, and have always been obliged to use a catheter to pass water. I calculate that I have passed catheters 80,000 times. I use steel and silk web instruments. I am now aged 56."

I think this account of long duration of catheter life is almost unique and worthy of record.—I am, etc.,

Manchester, June 22nd. JUDSON S. BURY.

PREVENTION OF RENAL COMPLICATIONS IN SCARLET FEVER

SIR,—Dr. B. A. Peters's letter in the *Journal* of June 20th states that by his (somewhat complex) method of treatment the complication rate for nephritis and albuminuria in his last 600 cases of scarlet fever was just over 1 per cent. This is admittedly a low figure. It can, however, be lowered still further, and, moreover, all the other complications of scarlet fever along with it.

During the last three years I have given Dick antitoxin intravenously to 832 cases. These have been "selected" only in the sense that they included all the worst cases—that is, nearly all definite cases admitted up to the fifth day of disease, and "septic" cases admitted up to the eighth day of disease. Exceedingly mild and doubtful cases were not included. The complications in this series have been: albuminuria 2, acute suppurative otitis media 5, arthritis (very mild) 3. Besides these there have been a small number of minor skin septic foci which can hardly be called complications. Excluding the latter, the total complication rate for scarlet fever in this series just exceeds 1 per cent. Such as they are, most of these complications occurred during a period of three or four months in 1930, when the dosage of antitoxin was insufficient. For all practical purposes one may claim that, by this method, the complications of scarlet fever can be abolished.

To many this may read like a fairy tale. Nevertheless, the facts can be demonstrated any day. The cases in the hospital at one time are never numerous, because they are discharged in eight to fifteen days. They are, moreover, quite well. There is practically no medical or nursing work involved except for the intravenous injection on the day of admission. Needless to say, adequate precautions have been taken to ascertain that complications do not, in fact, occur after the patients' discharge from hospital.—I am, etc.,

H. STANLEY BANKS,
Medical Superintendent.

Isolation Hospital and Sanatorium, Leicester, June 24th.

VITAMIN B CONTENT OF LIVER EXTRACT

SIR,—It appears to be generally accepted that all commercial liver extracts are deficient in the antineuritic factor of the vitamin B complex, although they are rich in vitamin B_2. A reference to this in an article by Dr. Lucy Wills (*British Medical Journal*, June 20th, p. 1059), quoting a verbal communication from Dr. Harriette Chick, prompts me to ask you to publish this preliminary note on certain experiments carried out in this institute during the past six months, from which it is clear that the vitamin B_1 content of liver extracts varies to an extent which renders any generalization in this connexion inadvisable. The results obtained indicate that proprietary liver extracts are divisible into two sharply defined groups: those which contain considerable quantities of the antineuritic factor B_1, and those in which B_1 is present in negligible amount. There is no intermediate class, if equivalents of fresh liver are compared, and the first category includes the majority of the extracts tested.

Eight different liver extracts, as used for the treatment of pernicious anaemia, were tested for their ability to promote normal growth in rats on a diet deficient in all water-soluble vitamins; of these eight extracts six were found to be efficient sources of vitamin B_1 as well as B_2. Three stomach preparations were also examined for their vitamin content, and all were found to be effectual in correcting a deficiency in both factors of the complex; presumably the stomach preparations, therefore, contain both B_1 and B_2.

The full experimental data will be published in due course. The results suggest that those liver extracts which are rich in B_1 as well as in B_2 should be included in the list of medicaments available for use in cases in which administration of the vitamin B complex is indicated. Clinical evidence can indeed be adduced that such extracts are of practical value as general tonics, a fact which may be partly attributable to their vitamin content.—I am, etc.,

Institute of Animal Genetics, Edinburgh, June 22nd.

MICROCEPHALY

SIR,—It seems that my question was justified, because it has led Professor Berry to give a very clear and detailed statement of the reasons for believing that most mental defectives have unduly small heads, and to explain that he has discarded belief in microcephaly as a type of defective. His reasons for the latter view are less categorical, but the negation is interesting. I imagine that no worker in the subject will dispute the frequency of "microcephaly" in Professor Berry's sense, but I believe he is in a minority in his rejection of microcephaly in its more usual sense as a type name. The proper classification of defective types is, of course, a matter of opinion, and might be the subject of an interesting discussion; but if types exist at all, or have any meaning, then I hold that the microcephalic is as clearly differentiated as the mongol, and has as real an existence. The standard English textbook seems to be quite clear in this teaching, but no doubt Dr. Tredgold would prefer to speak for himself rather than through quotation. While admitting Professor Berry's right to dispute the reality of the type, my question now becomes more simply defined: Is he justified in using the type name with a new meaning if the majority of students of the subject still adhere to the old usage?—I am, etc.,

London, S.W.17, June 22nd. NOEL H. M. BURKE.

REFRESHER COURSES FOR SHIP SURGEONS

SIR,—I would like to endorse Dr. Haslett Frazer's letter in the *Journal* of June 27th (p. 1139). After my war service I was for three and a half years a ship surgeon, most of the time in the P. & O. Company, and can speak from experience as to the value of Dr. Frazer's letter to any man thinking of going to sea as a surgeon. He must, however, be a surgeon in fact as well as in name. One must be prepared single-handed, and with no operating table other than a bunk or a temporary arrangement of boards, to deal with any surgical emergency. I have operated on most of the conditions Dr. Frazer mentions. In one voyage to New Zealand I can recall one confinement, two very bad septic hands, a fractured upper end of tibia, a (?) fractured lower end of femur (no x-rays available), fifteen cases of influenza, three of measles, and two of scarlet fever. Sea-sickness is common and troublesome, especially if the surgeon himself is also a sufferer. I found large doses of sodii bicarb. in plenty of hot water the best treatment.

I wish to take this opportunity of concurring with Dr. Frazer in his tribute to the staff of the shipping companies. In all the vessels in which I served, and while doing shore duty, I met with nothing but kindness and consideration, from the senior medical officer and marine superintendents to the lowest ranks of officers and men. I would strongly recommend any recently qualified man who can get a post as ship surgeon to go to sea for at least six months before settling down to his life's work. He will remember it to the end of his life, and will be a better man physically, socially, and professionally than he was before.—I am, etc.,

H. W. WEBBER, M.S., M.D.Lond.

King's Tamerton, Plymouth, June 27th.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The report and third reading on the Finance Bill were taken in the House of Commons this week, and the Bill increasing the loan to the Unemployment Insurance Fund passed through committee and report. The Lords discussed the Representation of the People Bill.

On June 30th the Sentence of Death (Expectant Mothers) Bill was read the third time and passed by the House of Lords.

In the House of Lords, on June 30th, the Bethlem Hospital (Amendment) Bill passed through committee without amendment and was reported to the House.

Scottish Health Estimates

Debate in the Commons

The Estimates for the Department of Health for Scotland were considered by the House of Commons on June 25th. Introducing them, Mr. WILLIAM ADAMSON said that from 1919 to May, 1931, 121,010 houses had been built in Scotland with State assistance, but the shortage of houses was still about 100,000. In 1930, 10,145 houses were approved for erection. Every effort was being made to secure more expedition in the erection of houses, and, if necessary, compulsory action would be taken against defaulting local authorities. Out of 227 local authorities 180 had submitted statements showing that 76,986 houses were required in their areas, and that they proposed to undertake a three years' programme, amounting to 52,174 houses. Forty-seven local authorities had not yet submitted statements making adequate provision for the housing needs of their area. Turning to national health insurance, Mr. Adamson said that the outstanding fact about the work of the scheme during 1930 was a drop in the payments for sickness and disablement benefit. The amount paid out was less per member than in any year since 1925. During 1930 some new forms of medical records were introduced, and a system by which the Department would receive details of all sickness occurring among insured persons. The preliminary reports which had been published in the annual report of the Scottish Department of Health were merely samples of the information which the Department would furnish when the scheme was in complete working order. Mr. Adamson referred to the administrative schemes which, under the terms of the Local Government Act, local authorities had submitted for his approval. The majority of these schemes provided for the removal out of the Poor Law of maintenance and treatment of mental defectives, provision for the health of expectant mothers, nursing mothers, and children under 5 years of age, the care of blind persons, and the provision for the treatment and clothing of school children. Mr. Adamson said he was disappointed that so little progress had been made in town-planning since the Act was passed in 1919. He called attention to the satisfactory vital statistics for 1930. Although some death rates were up (cancer, for example), some infections, and maternal mortality very slightly, the total death rate was only 13.2 in 1930, compared with 14.5 in 1929. The deaths of infants were 83 per 1,000, lower than the recorded rate for any year with the exception of 1923, which was 78.9. The tuberculosis death rate was a very satisfactory record also—88 per 100,000, compared with 94 in 1929. The progress made in fighting this disease was well illustrated by the contrast between the rate of 88 in 1930 and 124, at which it stood in 1920. For the first time since 1920 the birth rate had increased. These signs of improved health referred to a year of widespread unemployment. During 1930 the Health Department carried out an investigation of 100,000 school children in Edinburgh, Glasgow, Dundee, Aberdeen, and Lanarkshire. The results seemed to show that the social services were warding off the worst effects of this period of difficulty. On the whole, when beginning school life, and even on leaving school, children were better clothed and cleaner than in 1919, and suffered less from malnutrition, rickets, and defective teeth. The Government was devoting special attention to the development of an adequate hospital service. It looked to the local authorities to go forward with a policy which would end the old differentiations between the standard of treatment in Poor Law hospitals and that in fever hospitals or in the ordinary voluntary general hospitals. There was no justification for social differences in the treatment of the sick. The estimate of medical research into the causes of diseases had been increased in the Scottish Estimates this year from £100 to £2,500. It was intended that the scientific advisory committee should guide these investigations.

Sir JOHN GILMOUR agreed with Dr. Adamson that the health treatment of those who came under the Poor Law should be on a different and better footing. He thought that the step of linking the school and public health authorities would greatly facilitate the problem of dealing with the child of pre-school age. Scientific research in the matters of health should be brought quickly to the notice of local doctors.

Mr. R. W. SMITH said that if the statistics of maternal mortality were classified into smaller groups the House would be able to see the number of deaths in institutions, the number of cases where patients were nursed at home by a nurse and attended by a doctor, and the number where patients were nursed in their own homes and attended by a midwife. Mr. Smith approved the suggestion in the report of the Department of Health that systematic health home visitation should be applied in rural areas. He suggested that where a district nurse attended a woman in a maternity case she should also inquire about any children in that house under 5 years of age who had not been medically attended within the year, and should report upon them to the medical officer.

Mr. MACPHERSON asked whether the Health Department intended to assist poorly populated localities to get a telephone service installed to enable persons to get quickly into touch with the doctor. He also remarked upon the frequent lack in the houses of Highland doctors of a small additional room where patients might wait, or which could be used in an emergency for a slight operation. He asked the Secretary for Scotland to see what could be done in that matter.

Mr. MCKINLEY asked for an assurance that the medical arrangements under the Silicosis Act of 1930 should be amended so that victims of silicosis in Aberdeen, Orkney, and Shetland no longer had to travel to Newcastle-on-Tyne in order to be medically examined.

Mr. MACQUISTEN referred to dental disease in Scotland, and

said it was due to unsuitable food, and often from white bread.

Mr. McGOVERN spoke of overcrowding in Glasgow. Two million people in Scotland lived in one-apartment or two-apartment houses. In Glasgow 6,000 families lived in one-apartment houses, and most of these families numbered from six to twelve persons. In the notorious Calton area 160 children out of every 1,000 died before reaching the age of 12 months. He had discovered a case where a man, wife, and eight children under 14 lived in a single apartment house. Nine months previously a child who had been for two years in hospital as a tuberculous inmate had been partly cured and then sent back among the other children to give them that disease.

Sir FREDERICK THOMSON said that where home visiting could not be done by health visitors it was done by the district nurse. The infant mortality rate of 83 per 1,000 for Scotland in 1930 was better for any year except 1923, but the improvement was not so noticeable for the first week of life. For children between 1 and 5 years of age the death rate was 10 per 1,000, which was a great improvement over past years. The figure for maternal mortality was 70 per 1,000, which was regrettably high. It seemed certain that cases in past years which were due to puerperal causes, and which were not so described in the statistics, were now much more carefully described. He thought that the Local Government Act would improve the health of children between the ages of 1 and 5 by ensuring that from birth to the conclusion of school life the health of the child would be under one control.

Dr. WALTER ELLIOT said the annual report of the Department stated that a section taken out of the 1,850,000 insured persons in Scotland showed a lower morbidity rate during 1930 than in previous years. One of the important factors in that improvement was the absence of an influenza epidemic. The recurrence of such an epidemic had been one of the chief reasons for the rise which had perturbed all persons administering the National Health Insurance Acts for several years past. Scotland had been able to come through these years of depression and to show at the end of the period a lower infantile mortality, a lower tuberculosis rate, and an unimpaired standard of health of 100,000 children of unemployed people.

The Duchess of ATHOLL pleaded for the extension of maternity and child welfare schemes in the rural areas. Medical opinion agreed that one of the chief reasons for maternal mortality was the want of more ante-natal care. It was important to ensure that a nurse health visitor was within the reach of every mother and expectant mother. Only one-third of the mothers of Scotland got ante-natal care, and only one-quarter of the children up to 5 years of age got any medical care in the child welfare centres. One of the first things to be done for health in Scotland was to ensure that every county had district nursing associations with schemes by which the district nurses would advise mothers in regard to their own health and to the health of their children. Under the Local Government Act the whole of the scheme would be in the hands of the county council. She asked Mr. Adamson to appeal to the county councils to put themselves in touch with local nursing associations, which should federate and discuss with the councils how they could carry out child welfare and maternity welfare schemes.

Mr. ADAMSON then withdrew the motion that the Estimate be voted. This leaves the Estimate open for a possible further discussion.

Distemper

In reply to Mr. Freeman, on June 25th, Mr. CHARLETON said no complete statistics of the results of researches promoted by the *Field* Distemper Council concerning the inoculation of dogs against distemper were obtainable. The preparations were issued by a commercial firm to veterinary practitioners throughout the country. Inquiry was recently made, however, into the histories of some hundreds of foxhounds inoculated in 1928 and 1929. Taking only the twenty-three packs in which subsequent exposure to infection was certain, the incidence of distemper among inoculated hounds was found to be 1.4 per cent., and the death rate from this cause 0.3 per cent. Without inoculation the incidence of distemper among young foxhounds in this country approached 100 per cent., while the death rate was frequently 50 per cent., and might exceed 75 per cent. on occasion.

Foot-and-Mouth Disease

On June 29th Dr. ADDISON, in reply to Brigadier-General Brown, said that 922 cattle, 2,692 sheep, and 68 pigs had been treated with foot-and-mouth disease serum in the present outbreaks of the disease. It was too early yet to make any statement on the results of that treatment.

On June 30th Dr. ADDISON told Mr. Rosbotham that he was that day issuing instructions authorizing the removal under licence of the Irish animals which had been detained in landing places in Great Britain. He was also issuing that night an Order releasing a large part of Great Britain from the operation of the stand-still Order. The effect would be that in England and Wales there would be no restriction on the movement of animals, except in Northumberland, Cumberland, Westmorland, Durham, Lancashire, and the North and West Ridings of Yorkshire. In Scotland all parts of the country north of the Caledonian Canal would be free.

Small-pox in India

Mr. BENN, replying to Mr. Freeman on June 29th, said that 316 deaths from small-pox took place in Calcutta in 1924, 3,923 in 1925; 934 in 1926; 2,860 in 1927; 558 in 1928, 393 in 1929; and the provisional figure for 1930 was 1,831. The deaths in Bombay were: 1924, 1,231; 1925, 565; 1926, 476; 1927, 841; 1928, 595; 1929, 1,126; and 1930, 1,56 (provisional). In Madras the figures were: 1924, 196; 1925, 762; 1926, 60; 1927, 32; 1928, 246; 1929, 503; and 1930, 181 (provisional).

Tuberculosis and Infected Milk.—Mr. GREENWOOD told Mr. L. Smith, on June 19th, that there was no information available on which to base a reliable estimate of the number of cases of tuberculosis attributable to infected milk.

Housing in Scotland.—On June 23rd Mr. WESTWOOD informed Miss Lee that complete figures of the number of unfit houses in Scotland were not yet available. According to the statements that had been submitted by 180 local authorities, the houses required to replace unfit houses were 37,846, and the houses likely to be provided by those local authorities within three years to replace unfit houses was 24,321. He could not state the number of persons in Scotland living in condemned houses.

Grade A Milk.—Replying to Mr. Hurd, on June 25th, Mr. GREENWOOD said there had been a steady increase in the number of producers of Certified, Grade A (Tuberculin-Tested), and Grade A milk in England and Wales during recent years, but the number of producers of graded milk was still very small compared with the total number of milk producers in the country. In consultation with the Minister of Agriculture he was considering steps for encouraging public confidence in the purity of milk supplies.

Tinned Milk.—Mr. GREENWOOD told Mr. Perkins, on June 25th, that tinned milk marked "Unfit for babies" was so marked because it was lacking in milk fat, which was essential for babies. It was not otherwise objectionable on grounds of health. He could not take special steps to restrict its sale.

Change of Doctor.—Miss LAWRENCE informed Mr. Mills, on June 29th, that procedure with regard to change of doctor under the national health insurance scheme was altered, from April 1st, by the Medical Benefit Amendment Regulations, 1931. Those Regulations were laid before Parliament on February 17th. The department did not contemplate any revision of procedure.

Health of Mauritius.—Dr. SHIELS states that he will ask the Governor of Mauritius to obtain a report on the incidence of undernutrition in Mauritius. The report of the Registrar-General of Mauritius for 1930 on the mortality rate there has not yet been received.

Health Films.—On June 25th, replying to Mr. Mander, Mr. GREENWOOD said cinematograph films were frequently used by local authorities and voluntary bodies for instruction to the public on matters connected with health and mother-craft. Little use had so far been made of talking films for this purpose.

Obituary

DUDLEY W. BUXTON, M.D., M.R.C.P.

Consulting Anaesthetist to University College Hospital and the Royal Dental Hospital

We regret to record the death of Dr. Dudley Buxton, on June 28th, on his seventy-sixth birthday. He will be remembered by many doctors throughout the world for the work he did on anaesthesia, a subject which he made his life's study.

Dudley Wilmot Buxton was the second son of H. Wilmot Buxton, barrister-at-law, and was educated privately and at University College, London, and University College Hospital. He obtained honours in the M.B. and B.S. examinations in 1882, taking the M.D. in 1883 and the M.R.C.P. in the following year. After resident posts at University College Hospital, he worked for a time with Sydney Ringer, who was professor of medicine at University College. Their work was on the action of certain drugs on the heart. At this time he edited the fourth edition of Waring's *Therapeutics*. Starting the practice of anaesthetics in the early 'eighties, he confined himself to this subject from 1885 onwards. His early writings show his desire to investigate the scientific administration of ether and chloroform. His first publication in the *British Medical Journal* (September, 1885) was entitled "The practice of artificial anaesthesia, local and general, with special reference to the modes of production and their physiological significance." Nitrous oxide, ether, and chloroform attracted his attention in turn, and he made important observations on each. His work on nitrous oxide was largely due to an extensive experience at the Royal Dental Hospital, and in private practice for dental extraction, and to him is due the introduction of "continuous nasal gas." He was a strong advocate of the gas-ether induction for general anaesthesia, but little employed Shipway's apparatus. His work on colonic ether received little attention, but the recent development of avertin rectal anaesthesia was of great interest to him, and he felt that his early work may have influenced its introduction.

In 1901 the British Medical Association appointed Buxton honorary secretary of the Special Chloroform Committee, which issued an extensive final report in 1910. The particular subject of investigation was "To investigate methods . . . and to determine what is the universal dose of the drug (chloroform) which would secure an adequate anaesthesia for operations and at the same time not endanger life." As the outcome of this report, Dudley Buxton advocated the Vernon Harcourt apparatus, particularly for cerebral surgery. He had previously served on the Association's Committee on the Effects of Anaesthetics, appointed in 1891, and was a member of the Metropolitan Counties Branch Council from 1895 to 1898. His *Anaesthetics* reached its sixth edition in 1920, and is better known than the many monographs which he wrote in a literary style too rare amongst medical writers. He was anaesthetist to University College Hospital and the Royal Dental Hospital until his retirement in 1919, and had been anaesthetist to the National Hospital, Queen Square, and the Hospital for Women, Soho Square. During the great war he was anaesthetist to King George V Hospital. He was at one time president of the Society of Anaesthetists, of the Section of Anaesthetics at the Annual Meeting of the British Medical Association at Liverpool in 1912, and of the corresponding section at the International Medical Congress in London in 1913.

DUDLEY W. BUXTON, M.D.

As a teacher of anaesthetics Dudley Buxton's influence was considerable, and his great desire was that the doctor going into practice should have a competent knowledge of his subject, the teaching of which was neglected until the latter part of the last century. During his busy years he had a host of friends—surgeons with whom he worked, doctors who came to learn from him, and patients who appreciated his skill and his kindly words before the induction. He was one of the first anaesthetists who insisted on visiting a patient on the day before the operation if the case was likely to be a difficult one.

His interests, apart from anaesthesia, were mostly of a literary nature, and he was fond of his country cottage. After his retirement from London he lived in a house he had built in 1903 near Boxmoor. Of late years he took a warm practical interest in the work of the West Herts Hospital, administering anaesthetics and teaching the nursing staff. The welfare of nurses he always considered, and many will remember his parties for nurses from University College Hospital every summer.

He married Louisa, daughter of the Rev. Thomas Grey Clarke, in 1884, and his three sons survive him.

JOHN CARSWELL, F.R.F.P.S.GLAS., L.R.C.P.ED.

Late Medical Commissioner, General Board of Control, Scotland

By the death of Dr. John Carswell, formerly Commissioner of the General Board of Control for Scotland, on June 20th, at the age of 75, a distinguished and well-known figure in the world of psychological medicine has passed away.

John Carswell was born in Glasgow, and came of West

Highland stock. He studied medicine in his native city, and qualified in 1877. His first appointment, which gave a bias to his medical interests in after life, was that of assistant to Dr. James Rutherford, then medical superintendent of the newly erected Glasgow Mental Hospital, Woodilee. Dr. Rutherford was a man of original ideas and of forceful character. He was a pioneer of many movements for the greater freedom and better treatment of those suffering from mental disorder which became recognized features of Scottish procedure, such as the abolition of the "airing-court system" (there have never been any airing courts or padded rooms at Woodilee), the policy of the "open door," and occupation. From him Dr. Carswell obtained much of his inspiration.

Leaving Woodilee, Dr. Carswell was appointed a medical officer, first of the Barony and then of the Glasgow Parish Council. This office provided him with exceptional opportunities for the study of social questions, in which he took a deep personal interest. He devoted special attention to the condition of the homeless poor, to the question of the control of inebriates, and to the simplification of the procedure for dealing with mental disorder. He next induced the Glasgow Parish Council to place under his sole charge the certification of all alleged insane persons in a parish with a population of 600,000. This gave him a position and an experience unique in Great Britain, and he at once found grave anomalies, against which his rational and independent spirit rebelled. He found that cases of delirium tremens among the poor could only receive adequate treatment if certified insane and sent to the mental hospital, although they might be ill for only a week or two, and that cases of mild and incipient mental disorder, which from his personal experience he knew would also recover soon, had to submit to the same stigma of certification. The legal aspect of these cases, not their medical treatment, was evidently the paramount consideration. Further, he found that legal certification stood in the way of every attempt at early treatment, for the friends of those suffering from mild and early forms of mental disorder would not allow them to be certified.

Glasgow solved these problems by providing wards for the treatment of such cases in a new general hospital at Duke Street, and by placing these under the care of Dr. Carswell. There was thus initiated in 1890, by the inspiration of Dr. Carswell, the practice of treating early and recoverable cases of mental disorder without legal procedure or certification in the wards of a general hospital, but under the care of an experienced psychiatrist, assisted by trained mental nurses—a method of dealing with such cases now made permissible in England, and advocated under the provisions of the new Mental Treatment Act. The idea that the treatment of mental derangement without certification and legal intervention is a menace to the community in these days is a relic of the past, the bogy of a Victorian novelist (Charles Reade), from whose writings (*Hard Cash*) the public still accepts its information on mental treatment, in spite of the investigations of a parliamentary committee and of a Royal Commission, neither of which found a single sane person detained in any mental hospital.

In contemplating these developments one cannot avoid being struck by the great influence that Dr. Carswell must have exercised over the Glasgow Parish Council, and the confidence it must have reposed in him. He was loyally seconded by Mr. Motion, the inspector of poor. By careful study as a young man Dr. Carswell had developed into a very ready speaker. He was gifted with a logical and argumentative mind, and marshalled his facts in the most effective manner. His choice of words also was accurate, exact, and most appropriate. It is therefore not surprising to know that in 1896 he became a member of the Town Council of Glasgow, and he was able to make his influence felt over lay circles in a way that is seldom possessed by a medical man. All this was for the public good, because no one had a deeper or a fuller insight into the sufferings of the poor in sickness and in domestic difficulties than Dr. Carswell, from his personal experiences, and no one approached the solution of these with a clearer or more sympathetic mind.

Dr. Carswell, owing to his definite opinions and to the clearness with which he expressed them, was often employed in medico-legal cases, but the most interesting and dramatic case in his career was one in which he was involved himself. A Clyde pilot brought an action against Dr. Carswell and another physician for wrongous and careless certification. The pilot lost his case and appealed to a higher court, where the case was again given against him. It is interesting to record as evidence of the satisfactory methods employed in Scotland that this is the only action against a physician who has certified a patient ever brought into court since the Scottish Lunacy Act was passed in 1887, and, as is recorded, it was lost. The Clyde pilot was not satisfied with the result of his lawsuits, and determined to bring Dr. Carswell into court again, where he would be compelled to admit that the pilot had always been a sane man. He bought a revolver and fired three shots at Dr. Carswell, wounding him in the thigh. At the trial the Crown alleged that the prisoner was insane; but, for the defence, two physicians were prepared to say that he was not insane. The jury took the latter view, and found that he was not insane, and was guilty of an assault. The judge, Lord MacLaren, said that in effect the finding was one of common assault, but he would not take it from any jury that a man could buy a pistol fit to kill, and fire it three times into the body of another man, with the idea of inflicting only slight injury upon him, and he therefore sentenced him to penal servitude for ten years. As a matter of fact, one of the bullets passed within an eighth of an inch of the femoral artery. The prisoner was first sent to Peterhead, there found to be insane, and then placed in the criminal lunatic wards of Perth Prison, where he died insane.

Dr. Carswell was lecturer on mental diseases at the Anderson College Medical School. In 1924 he was appointed Maudsley lecturer of the Royal Medico-Psychological Association, and in 1928 Morison lecturer to the Royal College of Physicians, Edinburgh. He was interested in the problems connected with inebriety, in the views upon uncontrollable impulse and responsibility for crime, and in the physiological aspects of the causation of mental disorder, but he had little sympathy with psycho-analytic theories. In 1914 he was appointed a Commissioner of the General Board of Control, and retired about ten years ago.

Dr. Carswell's name will be remembered in the history of psychiatry for the practical measures he induced the parish of Glasgow to take to simplify and improve the early treatment of the mild and recoverable forms of mental disorder. These measures were afterwards adopted in other cities, and they played an important part in effecting changes in our laws, especially those of England. Every reformer will understand the amount of inertia that had to be overcome by him, some of it due to apathy, some to ignorance, and much more to the conservatism of human nature, and will ever hold Dr. Carswell's labours in very high honour. His home life was a happy one, and he was ably supported by Mrs. Carswell in all his difficulties. The one great blow in their lives, from which they never completely recovered, was the loss of a son in the war. He also leaves a son—a barrister—and a daughter, both of whom have literary tastes.

GEORGE M. ROBERTSON.

J. A. C. KYNOCH, M.B., LL.D., F.R.C.P.ED., F.R.C.S.ED.,

Emeritus Professor of Obstetrics, University of St. Andrews

Dr. John Alexander Campbell Kynoch, emeritus professor of obstetrics at St. Andrews University, who died suddenly on June 23rd at Birnam, was born at Forres, Morayshire, in 1863, and received his medical education at Edinburgh University, where he graduated M.B., C.M. in 1887. Deciding after graduation to specialize in midwifery and gynaecology, he had an extended course of study at the Universities of Berlin, Vienna, Bonn, and Munich. On his return to this country in 1889 he was appointed house-surgeon at Dundee Royal Infirmary, and, later, resident medical officer at the Glasgow Maternity Hospital. Thereafter he spent some time at the Rotunda Hospital, Dublin, and when the conjoint medical school of St. Andrews University was established at Dundee in 1898, he was appointed its first professor of midwifery, and became obstetric physician and gynaecologist to the Dundee Royal Infirmary.

For many years Professor Kynoch acted as dean of the Faculty of Medicine at St. Andrews University, which, after his retirement in 1928, conferred upon him the degree of Doctor of Laws. He was elected a Fellow of the Royal College of Physicians of Edinburgh in 1897, and obtained the F.R.C.S.Ed. in 1904. He was a Fellow of the Edinburgh Obstetrical Society and of the Glasgow Obstetrical and Gynaecological Society, as well as a corresponding member of the Munich Gynaecological Society, and he acted as a vice-president of the Obstetrical Section at Annual Meetings of the British Medical Association in 1910 and again in 1914. He was also an examiner in midwifery for the Universities of Glasgow and Durham, and contributed extensively to the literature of gynaecology and obstetrics.

HENRY JOHN BLAKESLEY, F.R.C.S.

Consulting Surgeon, Leicester Royal Infirmary

Long associations with the medical and surgical life of Leicester have been severed by the death of Mr. H. J. Blakesley, F.R.C.S., consulting surgeon to the Leicester Royal Infirmary. Mr. Blakesley settled in Leicester as far back as the year 1889. After a short time he became attached to the old Leicester Provident Dispensary as one of its surgeons, and soon after was appointed assistant surgeon to the Royal Infirmary, becoming honorary surgeon in 1901. In 1919, on attaining the age of 60, he was elected consulting surgeon. During the years of the war he served on the staff of the 5th Northern General Hospital, with the rank of major, and was placed in charge of beds at the Royal Infirmary which were devoted to the treatment of wounded soldiers. In 1916 he was appointed medical officer in charge of the newly established Venereal Diseases Department at the Royal Infirmary, a position which he held to the day of his death—indeed, it was while he was actually in the wards of that department that the fatal seizure took place. He was a vice-president of the Section of Surgery when the British Medical Association met at Leicester in 1905, and he had been chairman of the Leicester Division and president of the Leicester Medical Society.

Like many other provincial surgeons of his day Mr. Blakesley was engaged in general practice for the greater part of his professional life, and was to a remarkable extent the friend and confidant of his patients. He was a man of fine courage, and came undaunted through several set-backs caused by illness and misfortune. The news of his sudden death came as a painful shock to his colleagues, and the respect and esteem in which he was held was shown by the large attendance at the funeral service at the church of St. John the Divine, with which he was closely associated for many years.

Dr. WILLIAM DARLING, a well-known practitioner of Edinburgh, died in that city on June 23rd. Born in 1871, he received his early education at the Royal High School and George Watson's College, Edinburgh, and, taking the M.A. degree of Edinburgh University, qualified as a teacher. Shortly afterwards he determined to study medicine, and graduated M.B., Ch.B. at Edinburgh in 1899. Thereafter he became house-surgeon to Leith Hospital and resident medical officer to the Chelsea Hospital for Women, and studied for a year at Marburg University. On his return to Edinburgh he took the Fellowship of the Royal College of Surgeons in 1903, and its D.P.H. in 1906. From 1903 he was busily engaged in general practice in the south side of Edinburgh up to within a few weeks of his death. For some twenty years he held the post of medical officer and lecturer in hygiene to the Edinburgh Provincial Committee Training College for Teachers at Moray House, and during this period many hundreds of students passed through his hands. He saw much war service, being in South Africa during the Boer war and afterwards associated for over twenty years with the medical unit of the Edinburgh University O.T.C., of which he was commanding officer for some years prior to 1914. As an officer of the Special Reserve he was sent abroad almost immediately after the outbreak of the war, and served in France and Flanders till after the armistice, when he held the rank of Lieut.-Colonel in the R.A.F. Medical Service. For services on the Somme he was awarded the Military Cross. Dr. Darling is survived by a widow and four children.

The death took place at his residence, Dean Park Crescent, Edinburgh, on June 25th, of Dr. ROBERT SHAND TURNER, whose family had long been connected with medical practice in Banffshire. Dr. Turner was born in 1846, and received his early education at Aberdeen, where he took the M.A. degree in 1864. Proceeding to Edinburgh to study medicine, he graduated M.B., C.M., and also obtained the L.R.C.S.Ed. in 1867, and the degree of M.D. in 1870. After being a demonstrator of anatomy at Edinburgh University under Professor Goodsir, and resident medical officer in the Royal Hospital for Sick Children, he joined his father, Dr. Robert Turner, who had been for nearly half a century in practice at Keith, Banffshire. Father and son conducted a practice between them for nearly a century in this district, the son contributing fifty-one years. Dr. R. S. Turner was medical officer of health for the burgh of Keith, and was the first medical superintendent—from 1880—of the Turner Memorial Hospital, which had been erected by the inhabitants of Keith and the surrounding districts in memory of his father. He was a keen Volunteer, and acted as Surgeon Lieut.-Colonel of the 6th V.B. Gordon Highlanders. He took a considerable interest in the local work of the British Medical Association, and was past-president of its Northern Counties Branch. On his retirement from practice in 1921 he resided in Edinburgh. He is survived by a widow, a son, and two daughters, one of whom is a graduate in medicine of the University of Edinburgh.

The death occurred at Middlesbrough of Dr. WILLIAM KNOTT, who was the senior practitioner in the town and district. Dr. Knott was born at Wolverhampton in 1857. He was educated in Middlesbrough and afterwards at Edinburgh University, graduating M.B., C.M., and later M.D. He settled in practice at North Ormesby, Middlesbrough, and acted as house-surgeon to the North Ormesby Hospital during a long period of years until that institution became large enough to require a resident. When that took place Dr. Knott was appointed to the honorary surgical staff, and served in that capacity for many years before he retired and was elected to the consulting staff. Dr. Knott served in many other public offices. He was medical officer of health to the North Ormesby Urban District Council before that area was absorbed by the borough of Middlesbrough. He was a public vaccinator, and honorary medical officer to Dr. Barnardo's Home and

to North Ormesby Orphanage. He was a member of the British Medical Association and of the Society of Medical Officers of Health, and was a life member of the St. John Ambulance Association. Dr. Knott is survived by a widow and one son, the deputy coroner for the county borough of Middlesbrough.

The following well-known foreign medical men have recently died: Dr. EUGÈNE BODIN, professor of bacteriology at the Rennes Medical School and an authority on dermatomycoses; Dr. G. COLDEFY of Paris, director of the office for the repression of the illegal practice of medicine; Dr. DONATIEN RAFFEGEAU of Paris, president of the Société de Psychologie; and Dr. MONNIER, professor of clinical medicine at the Nantes Medical School.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

THIRD M.B., B.CHIR.—(*Part I, Surgery Midwifery, and Gynaecology*): R. J. V. Battle, H. E. Blake, E. Bradbury, A. B. Carter, G. T. Cook, A. H. Dunkerley, K. V. Earle, G. R. Ellis, C. D. Evans, C. L. Ferguson, T. C. Gipson, D. R. Goodfellow, H. F. Green, G. W. Hall-Smith, A. S. Herington, J. Howell, J. Hughes, J. T. Irving, N. M. James, L. P. Jameson Evans, R. A. Jones, A. W. Langford, A. Lister, B. F. Longbotham, J. V. Lucas, G. C. Martin, F. C. Mayo, D. A. Metcalf, A. K. Monro, J. G. More Nisbett, G. G. Mowat, R. W. C. Murray, W. H. Mylechreest, C. R. L'E. Orme, J. L. Parker, G. T. Partridge, C. G. Roberts, I. C. Robertson, E. Sharp, N. Stevens, R. A. Sykes, J. E. J. Thomas, G. M. Tickler, A. B. Waters, M. Westwood, C. E. R. Wood, A. H. Zair. (*Part II, Principles and Practice of Physic, Pathology, and Pharmacology*): C. P. Bailey, G. N. Bailey, J. S. Barker, L. T. Bond, C. C. Bryson, H. S. Buckland, G. F. Carey, A. B. Carter, C. L. Collins, G. T. Cook, J. H. Cyriax, A. Eckford, W. A. Fell, D. R. Goodfellow, F. T. J. Hobday, J. I. Irving, G. D. Kersley, C. R. T. Lane, D. L. Lewis, J. W. S. H. Lindahl, G. G. Ludgater, E. H. W. Lyle, D. B. McGavin, J. M. Matthew, C. W. Morley, W. M. Niblock, R. G. Orr, J. L. Parker, J. Petro, W. H. Poole, H. E. W. Roberton, M. H. Salaman, G. H. Sanderson, W. W. Sargant, P. G. Scott, J. Sowerbutts, J. H. Spence, T. C. Stamp, E. T. W. Starkie, H. C. Stewart, J. W. Summerhayes, A. W. Vaisey, J. G. Vincent Smith, E. D. Ward, G. W. Whittall, L. K. Wills, T. D. G. Wilson, C. H. Wrigley, R. H. Young.

NATIONAL UNIVERSITY OF IRELAND

At an extraordinary meeting of the Senate, held on June 25th, it was decided that the degree of Doctor of Science (D.Sc.) *honoris causa* should be conferred upon Professor John Joly, Sc.D., F.R.S., in view of his scientific attainments and of his presidency of the Royal Dublin Society in the year of its bicentenary.

The Services

OPERATIONS ON THE NORTH-WEST FRONTIER

The following are among the names brought to notice by Sir William Birdwood, late Commander-in-Chief in India, for distinguished services rendered during operations on the North-West Frontier of India during the period April 23rd to September 12th, 1930: Colonel L. P. Brassey, I.M.S., Assistant Director of Medical Services, Peshawar District; Major M. P. Power, O.B.E., *M.C.*, R.A.M.C.; Captain H. J. Rice, O.B.E., *M.C.*, I.M.S.

DEATHS IN THE SERVICES

Colonel James Maybury Beamish, late R.A.M.C. (ret.), died at Drumdalcagney, County Cork, on April 21st, aged 86. He was born on January 26th, 1845, was educated at Queen's College, Cork, and at Bart's, and graduated as M.A. in 1865, and as M.D. and M.Ch. in 1868, in the Queen's University, Ireland. He also took the M.R.C.S. and M.K.Q.C.P. in 1871, and the D.P.H.Camb. in 1891. Entering the Army as assistant surgeon on April 1st, 1871, he attained the rank of colonel on December 9th, 1898, and retired on January 26th, 1905. As a regimental officer he served in the 48th Foot, the Northamptonshire Regiment. He served in the Afghan war of 1878-79, in Dadur and in the Bolan Pass, gaining the medal, and in the Burmese campaigns of 1885-86, receiving the frontier medal with a clasp. He was also re-employed during the war of 1914-18. He had a considerable reputation as a linguist, and was said to know seven languages, European and Oriental.

Medical News

His Majesty, accompanied by the Queen, will open the new King George Hospital at Ilford on Saturday, July 18th, and they will take this opportunity of visiting the hospital health centre on the London County Council's estate at Becontree.

The annual dinner of the British Medical Association will take place at the Grand Hotel, Eastbourne, on Thursday, July 23rd, at 7.30 p.m. As the accommodation is limited, it is desirable that members wishing to have tickets reserved should notify the Honorary Secretary, Eastbourne Meeting, Avenue House, Eastbourne, at the earliest possible date. Tickets will be allotted strictly in order of application. Vouchers entitling members to take advantage of the facilities offered by the railway companies of Great Britain can be obtained on application to the Financial Secretary of the Association. The companies will issue return tickets available from July 14th to 27th inclusive at the ordinary single fare and a third for the double journey.

A dinner of the Medical Society of Individual Psychology will be held at the Florence Restaurant on Thursday, July 9th, at 7.30 p.m. (morning dress), and will be followed by the general meeting.

At a meeting of the Victorian Branch of the British Medical Association, held on May 6th, Dr. E. R. G. Sheil, resident medical officer of the Ballarat Hospital, received from the hands of the president a cheque for £25, being the prize for an essay by final-year medical students of the Empire other than those of the British Isles, awarded by the Association in England. Occasion was taken at the same meeting of the Branch to congratulate Dr. Edgar King, F.R.C.S., the winner of the Jacksonian Prize for 1930, awarded by the Royal College of Surgeons of England (see *British Medical Journal*, April 18th, p. 689).

Detailed information about the lectures and demonstrations arranged for next week by the Fellowship of Medicine and Post-Graduate Medical Association will be found at page 20 of the *Supplement*. An intensive course in medicine, surgery, and the specialties will be held at the Prince of Wales's General Hospital, Tottenham, from July 6th to 18th; fee £5 5s. A similar course will be given at the Miller General Hospital from July 20th to August 1st; fee £3 3s. These courses will occupy the whole day, from 10.30 a.m. to 5.30 p.m., and are especially intended for general practitioners, and those needing a revision course. Syllabuses and tickets for all the courses may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The thirteenth Carlsbad International Medical Educational Congress, with Special Reference to Balneology and Balneotherapy, will be held from September 13th to 19th. Thirty papers have been so far submitted on the more important hydrological aspects of internal medicine and associated surgical problems. Dr. P. Manson-Bahr (London) will give an address on the "Dawn of tropical medicine," illustrated by the main discoveries of Patrick Manson. Visitors to the congress will be guests of the town, and will be afforded every opportunity of studying the methods of treatment adopted in the Kur establishment; they will also obtain a 33 per cent. reduction on the Czechoslovakian railways. Further particulars may be obtained from Dr. Edgar Ganz, the business manager in Carlsbad.

At the annual general meeting of the London Jewish Hospital Medical Society, held on June 25th, with the president, Dr. L. Mandel, in the chair, the reports of a very successful year's activities were submitted by the hon. general secretary, Dr. L. Phillips, and the treasurer, Dr. L. Turiansky. Dr. M. Sorsby was elected president for the session 1931-32, and other officers were appointed.

A French society of gynaecology has been recently founded in Paris. Further information can be obtained from the president, Dr. F. Jayle, 20, Rue Cassette, Paris 6e.

The twenty fifth anniversary of the discovery of the Wassermann reaction was celebrated on June 1st at the meeting of the Kaiser Wilhelm Society for the Advancement of Sciences in Berlin by Professor Felix Plaut, who delivered an address on the theoretical foundation of the Wassermann reaction

Under the auspices of the Central Association for Mental Welfare a course will be held from August 29th to September 19th for persons engaged in the training of mental defectives in occupation centres, institutions, or mental hospitals There will be lectures on mental deficiency including the recognition of its various types, study of the growth of the child, and the general methods of promoting the development of speech and correcting defects Classes will be held in occupational handicrafts such as basket making, pottery, weaving, and woodwork, and instruction will be given in rhythmic training including country dancing and singing games specially adapted to the needs of defectives The fee for resident students is £14, and for the non resident, £6 10s , hostel accommodation has been secured Early application for the course is essential, and forms must, in any case, reach the office of the Central Association by July 20th The registration fee is 5s Further information may be had from the honorary secretary of the Central Association for Mental Welfare, 24, Buckingham Palace Road, S W 1

The returns from universities and university colleges in receipt of Treasury grant for the academic year 1929–30 has been issued by the University Grants Committee (H M Stationery Office, 1s 3d) In its introductory note the committee observes that the total number of full time students in the universities and colleges to which this publication relates continues to grow, though the proportion of women to men students has tended to fall slightly in recent years The distribution of full time students over the various subject groups reveals no change in the general tendency observable for several years past The percentage relations of the various groups to the total in 1929–30 were arts 53 4, medicine 19 1, pure science 16 5 technology 9 1, agriculture 1 9 In the medical group the men students increased by 310, women by 23 It is noted that the decline in the number of men medical students which had been continuous since 1923–24 came to an end with 1927–28, the next year showing an increase of 20s, and the year under review a further increase The schedule of degrees and diplomas obtained during the year and analysed according to faculties gives a total of 902 degrees and 971 diplomas under "Medicine, including dentistry" in Great Britain Full time medical and dental students numbered 8,759, of whom 7,623 were men and 1,136 were women

The London Light and Electrical Clinic in Ranelagh Road S W , of which the governing body is now the Order of St John of Jerusalem, has been put under the supervision of Sir Leonard Hill, F R S , who is also director of research and teaching at the clinic On the advice of the Medical Advisory Board, of which Sir William Willcox is chairman, honorary consultants have been appointed by whom all new patients are examined A staff of specialists in the methods of physical medicine control the treatments which are carried out by State registered nurses Payments are proportionate to the means of the patients, and are arranged by the lady almoner For those able to pay higher fees a private department is available Some 2,500 treatments are now given every week at the clinic

The issue of the *New Zealand Medical Journal* for February, 1931, contains the text of an address on cancer in relation to the air and food passages, which was broadcast by Dr James Hardie Neil for the Auckland Cancer Committee of the local Division of the British Medical Association

The issue of *Il Morgagni* for June 28th is devoted to the memory of G B Morgagni, who was born at Forlì in 1682 and died in 1771 Tributes are paid to his wide outlook and his influence on the progress of medical knowledge, as well as to the special researches for which his name is famous, and his famous treatise in five volumes, *De sedibus et causis morborum per anatomem indagatis*, which he published in 1761, at the age of 79

The current number of *Antiquity* is, like its predecessors, of varied intellectual interest An editorial note pleads for the endowment of a chair of Old English archaeology, and suggests that the necessary funds might be made available "by abolishing a few of the many useless professorships that abound" One of the articles describes the Peruvian scene on which the remarkable civilization of the Incas was superimposed , another comments on the evidences for "Noah's Flood" Under the heading of "Notes and News" is a reference to the study of fluorescences emitted by the inks of manuscripts when examined under ultra violet rays The ink used in papyri and such inks of later periods as contain gallic acid have been found so far to be inert to the rays, but some instructive results have been reported by workers who have employed this method in deciphering Chaucerian manuscripts At the Louvre the rays have assisted in revealing signs of retouching, and have proved apparently several supposed originals to be copies As they are evidently capable of exposing the brushwork of the artist, they may conceivably be a valuable aid in studying the technique of some of the old masters The great advantage of the ultra violet group of rays is that no damage is done to the painting during the examination

Professor Hans Spitzy of Vienna has been made an honorary member of the British Orthopaedic Association

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square W C 1 on receipt of proofs

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange four lines)

The **TELEGRAPHIC ADDRESSES** are

EDITOR OF THE *BRITISH MEDICAL JOURNAL* *Aitiology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc) *Articulate Westcent London*

MEDICAL SECRETARY *Mediscra Westcent London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus Dublin*, telephone 62550 Dublin), and of the Scottish Office 7, Drumsheugh Gardens, Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Frequent Micturition

"FIDES" asks for suggestions in the treatment of a patient with too frequent micturition during the daytime The urine contains no albumin or sugar specific gravity 1022 The usual remedies have been tried

Pyrexia after Confinement

"A E " writes With reference to J D s query June 20th p 1099) may I suggest that the urine be examined for bacilluria I had a similar case the patient's temperature and general condition cleared up very soon on a mixture of potassium citrate 30 grains every four hours, continued for about a fortnight

Urticaria

Dr BRUCE MACLEAN (Newcastle under Lyme) writes I suggest the administration of oxygen given subcutaneously in doses of 300 to 500 c cm per diem This is best injected by means of the Baveux apparatus but can be given from ordinary cylinders through rubber tubing and hypodermic

needle, provided the volume of escaping gas is sufficiently controlled The most suitable site for injection is the outer aspect of the thigh , a raised area of tissue equivalent to the size of a small saucer roughly indicates 200 c cm. of injected oxygen I have known subcutaneous oxygen to clear up urticaria rapidly, and also in cases where the usual therapeutic methods have failed. In one case the urticarial eruptions had advanced to such a degree as to involve the base of the tongue and larynx in addition to face and body areas , one injection of oxygen was sufficient to abate the symptoms. No doubt every focus of infection has been investigated by "Practitioner," including *x*-ray examination of the apices of the teeth. I know of one case of chronic urticaria where the symptoms were due to apical sepsis, for they entirely disappeared after the dental abscess was eradicated The fact that "the vaccine helped a little" is suggestive of streptococcal infection. I am not aware if anyone else has tried subcutaneous oxygen in urticaria, but it is well known, especially on the Continent, for the relief it gives in the early stages of asthma, which is another allergic disease. For full information on this subject see *The Nature of Disease*, Parts I, II, and III, by J E R McDonagh.

Surgeon Commander G. V HOBBS, R.N., writes: I would suggest that "Practitioner" tries one or two injections of novarsenobenzol, 0 45 gram, intravenously, with seven days' interval beween injections. I have cured two obstinate cases of urticaria by this method, and think it worth a trial.

Effect of Prolonged Injections of Insulin on Subcutaneous Tissue

"M D" writes I have been much interested to read the letter of Dr W W Jeudwine (June 27th, p. 1145) about the effects of injections of insulin, as only four days ago I came across a case similar to the one he records. This lady whom I have just seen had been in the habit of giving herself two injections daily, alternately in either upper arm just above the elbow. The effect was striking. The shaft of each upper arm showed a degree of emaciation which was in marked contrast with the apparently huge overhanging deltoids , these assumed almost Sandow-like proportions, though the patient was actually not muscular, but rather the reverse. Like Dr. Jeudwine, I do not know whether such local action of insulin is common. It would be interesting to have the opinion of somebody who has an extensive experience with diabetics

Income Tax

Life Assurance Statutory Income

"I S R" inquires what is the basis on which total statutory income has to be calculated in order to ascertain the maximum allowance of one-sixth of that total.

*** The total statutory income for any year is the total income on which the taxpayer is liable to bear income tax for that year Earnings are assessed for one year on the basis of the amount of the income of the previous year ; income taxable by deduction, such as dividends and mortgage interest, is taxed on the actual amount receivable in that year Consequently, the total statutory income for the year 1930-31 is the aggregate of, for example, the salary earned in 1929 30 plus the dividends, etc , receivable in 1930-31 As "I S R" points out, the latter are not necessarily known, either to the taxpayer or to the authorities, until the end of the year, and for that reason irritating adjustments sometimes fall due in applying the one-sixth restriction to the life assurance relief.

LETTERS, NOTES, ETC.

Medical Patents

Correction

We hasten to correct a printer's error in the letter by Dr. H H DALE on "Medical Patents," published in last week's *Supplement* (p 268, column 1, line 23). As the context plainly shows, the sentence should have read "I know that they can only do this by making it clear that they will have nothing to do with *patents* on the one hand, or secrecy on the other."

Sugar in Dietetics

Dr D C NAISMYTH (Walmer) writes. Now that sugar is found to play such an important part as an aid to the digestion of fats and in the prophylaxis and treatment of so many diseases, I am sure there must be many practitioners like myself who would be glad to be informed by the experts as to how much is known about the value of the various forms of sugar as regards the human body. What are the facts of "cane sugar *versus* beet sugar," and of "artificial sugars such as glucose *versus* natural sugar"? Is the chemically ultra-refined and often artifically coloured sugar on the market of equal value with the natural pure sugars? The difficulty of settling these questions is enhanced by the fact that feeding experiments on animals with regard to sugar are of little value. Sugar not being a natural form of food to any except insects, I am informed, though I cannot vouch for the accuracy of the statement, that bees cannot flourish on pure beet sugar I am using the term cane sugar to designate sugar from the cane, though the physiological chemists employ it to include beet sugar, etc., and I am never very sure in which sense the term is used by medical writers. I am informed from a reliable source that the sugar on the market in this country is mainly of sugar-cane origin—that is, the proportion of cane to beet sugar is about 4 to 1. I know one large school whose head takes the trouble to feed the children on pure cane sugar—being convinced of its superiority dietetically, though slightly more expensive. Glucose, a highly artificial form of sugar, is, I imagine, so popular in treatment, partly because it is the form of sugar actually absorbed from the alimentary canal, and partly because, not being so sweet as other sugars, more can be given without nauseating the patient. Except for its administration intravenously or per rectum, do these advantages outweigh the disadvantages of it being a purely artificial sugar and not nearly so palatable as pure cane sugar? Children in good health will generally take a large amount of cane sugar without objecting to its sweetness We do not often give peptone instead of protein because it is the form most easily absorbed. The whole trend of modern dietetics is to employ the natural forms of food in preference to the artificial. Is sugar an exception to this conception? Again, modern medicine advocates more sugar in the diet of the child, while dentists are against sugar. During the war, when sugar was scarce, the school dental clinics noted a large decrease in dental caries, and this in spite of a deficiency in the food of vitamin A. Will anyone be kind enough to explain these things to me?

Femoral Thrombosis in Pneumonia

Dr. T. STENNER EVANS (Swansea) writes: I was interested to read in the *Journal* (June 27th, p. 1146) an account of thrombosis of the femoral vein following pneumonia. In 1922 I published the notes of a similar case. My patient fortunately recovered from her illness, but two years later had a second attack of pneumonia, which was again complicated by femoral thrombosis, and on this occasion by pulmonary infarction also. She was very dyspnoeic for some hours and had severe pain in the left chest, but after twenty-four hours breathing became less dyspnoeic, and the patient ultimately recovered. My reason for quoting this case is that, although femoral thrombosis as a complication of pneumonia is comparatively rare, a repetition of the whole process, with ultimate recovery, appears to be very rare.

A Grenfell Calendar

An attractive calendar for 1932 is being prepared by the Grenfell Association, for the benefit of Sir Wilfred Grenfell's work in Labrador and Northern Newfoundland. A frontispiece in colour shows Sir Wilfred on the bridge of the hospital steamer *Strathcona*, and there is a page for each week, containing a reproduction from a photograph of Labrador. If this calendar proves a success it is hoped to repeat it each year The price in Great Britain is 3s. 6d ; packing and postage 6d. extra. Orders should be sent to the Grenfell Association of Great Britain and Ireland, 82, Victoria Street, S W 1.

A Sterilizable Telephone Disk

An old member of the British Medical Association has invented a simple device for disinfection of telephone mouthpieces It consists of a small metal reversible disk, which can be clipped on to vulcanite or glass mouthpieces Its greatest advantage is the ease of application ; this allows daily sterilization by boiling. We understand that supplies can be had from C Wilkinson, 64, Church Road, Upper Norwood, at 1s each, or by post 1s. 3d.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *19*.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Myocardial Infarction

In a discussion of the clinical and pathological aspects of myocardial infarction M. REGNIER and L. DESCLIN (*Rev. Belge des Sciences Méd.*, January, 1931, p. 1) recall the fact that rich anastomoses unite the branches of the coronary arteries and the vasa vasorum of the aorta and pulmonary artery. A twig from the right coronary is the principal blood supply to the conducting system. The most dangerous consequences of infarction are derangements of rhythm, and immediate or late aneurysm formation. Coronary obliteration occurs either abruptly through embolism, or gradually as a result of decrescent coronary disease or syphilitic aortitis. Infarction resulting solely from vascular spasm has been observed in cases of epilepsy. The authors comment on the great frequency of myocardial cicatrices discovered at necropsies even when there has been no history of thoracic pain. The patients described in their present communication showed the usual symptoms and signs; it is believed that leucocytosis continuing after about six days indicates an extension of the necrotic process. Pericardial friction is discovered in a minority of cases, and when present is often variable and transitory. Among the disorders of rhythm observed were extrasystoles, paroxysmal tachycardia, auricular fibrillation, and the various grades of heart-block. The electrocardiographic findings were in general agreement with those established by other workers—an initial elevation or depression in the ST interval, the coronary wave, and ultimate T-wave inversion. These changes appear more gradually, clinically, than in the experimental animal. It is believed that previous coronary sclerosis and circulatory disorder in the first case is responsible for the difference. Recent records taken after traumatic injury to the heart in healthy individuals support this view. The authors hold that the prognosis in cardiac infarction is not so good as is generally believed, and that about two-thirds of all patients die.

2 Acquired Pulmonary Stenosis

Recording a case of acquired pulmonary stenosis, G. DE F. TRAVASSOS (*Rev. Sud-Amér. de Méd. et de Chir.*, April, 1931, p. 373) first discusses the differential diagnosis of the various cardiac murmurs. In pulmonary stenosis the right side of the heart is dilated, thus pushing the apex towards the left axilla; the systemic circulation is but little if at all involved, and the disturbances are concentrated in the lungs, giving rise to such symptoms as dyspnoea. The left side of the heart and the aorta become atrophied. The pulmonary artery below the constriction is generally dilated. Radiography provides a confirmatory sign, the heart assuming the shape of a Dutch sabot. The condition results from an endomyocarditis, the exciting cause of which is unknown. Acute articular rheumatism is not an important factor; the eruptive fevers, tuberculosis, syphilis, and traumatism of the precordial region play a part also. Travassos agrees with Hatzieganu that two mechanical factors produce the stenosis—hypertension, which causes distension; and stasis and increased volume of blood, which give rise to hypertrophy and dilatation of the right heart. The poor pulmonary circulation, by modifying the lung tissues and disturbing the intra-alveolar gaseous exchanges, favours the development of tuberculosis. The patients are usually of a robust appearance and apparently in good health; they show merely a slight facial pallor, dyspnoea on effort, which varies with the degree of stenosis, and a dry, metallic cough, also increased by exertion. As the ventricle becomes weaker and dilates, such signs as cyanosis, increased dyspnoea, oedematous pulmonary congestion, blood streaks in the sputum, true haemoptysis, and pleurisy occur. The patient may die after frequent attacks of syncope, or suddenly from pulmonary embolism or thrombosis. In most cases, however, tuberculosis with its physical signs supervenes before these asystolic symptoms appear.

3 Intracranial Aneurysms

Though intracranial aneurysms are not common, they are not very infrequent; the prognosis is bad, especially when they have begun to bleed, but the possibility of effective surgical therapy must be considered. M. SCHMIDT (*Brain*, January, 1931, p. 489) presents a study of this disease based on 23 cases which have occurred during the past fifteen years. The frequency, age incidence, and position of intracranial aneurysms are discussed; these apparently vary according to different authors. The etiology also is differently stated; congenital anomalies, local diseases in the arterial wall, traumata, arterio-sclerosis, etc., have been regarded as the most essential factors, and syphilis as unimportant. In the present series of cases Schmidt found neurosyphilis in four and arterio-sclerosis in eleven; he concludes that arterio-sclerotic aneurysms are frequent and those of syphilitic origin relatively rare. The symptoms of these aneurysms must be distinguished from those of the original disease—as, for example, arterio-sclerosis. The clinical symptoms vary, and in most cases are either not characteristic or are totally absent. Focal and local symptoms are rare, owing to the slow growth and yielding nature of the aneurysms. Symptoms of intracranial hypertension, unless bleeding has occurred, are seldom found. A frequent characteristic symptom is severe headache on the same side. All aneurysms eventually cause a subarachnoid haemorrhage with its attendant symptoms. Treatment of these aneurysms has been unsatisfactory; owing to diagnostic difficulties it must, as a rule, be conservative. Gelatin injections may have some effect in bleeding aneurysms. Lumbar puncture, important in other forms of subarachnoid haemorrhage, is dangerous and should be employed with caution and reserve. Greater knowledge of the clinical and *x*-ray features may aid diagnosis and increase the therapeutic possibility.

Surgery

4 Non-parasitic Cysts of the Liver

F. D. ACKMAN and L. J. RHEA (*Brit. Journ. of Surg.*, April 19th, 1931, p. 648) describe a case of haemorrhage into a non-parasitic cyst of the liver. A woman, aged 61, had had attacks for thirty-five years, which were characterized by a sense of weight in the epigastrium, eructations of gas, nausea, and vomiting. These attacks usually cleared up spontaneously after a few hours, but before admission to hospital a very violent pain had been experienced across the upper part of the abdomen, and there was swelling and tenderness in the right upper quadrant. Operation was undertaken and a dark-bluish globular cyst was discovered projecting from the anterior margin of the right lobe of the liver. The free surfaces of the cyst were covered with thickened peritoneum, and on palpation the cyst was found to extend some distance into the liver substance, involving the postero-inferior surface of the right lobe. A smaller cyst was seen on the superior surface of the right lobe of the liver. Both cysts were punctured, 5 c.cm. of clear amber fluid being withdrawn from the small cyst and 500 c.cm. of chocolate-coloured cloudy fluid from the larger one. Recovery was uneventful; the larger cyst was entirely obliterated, and the small one healed in five days. The pathological diagnosis was made of non-parasitic cysts of the liver of the bile duct type, with haemorrhage into the larger one and

a consequent acute inflammation. The most common location of these cysts is the antero-inferior margin of the liver; consequently pressure from their enlargement most frequently involves the gastro-intestinal tract. The larger cysts are often pedunculated; they may show a marked degree of mobility, though downward displacement is limited by the liver attachment. The diagnosis is seldom made before operation, since the symptoms are usually slight, and it is only when a complication such as haemorrhage, or an acute infection, arises that surgical treatment becomes necessary. When extirpation of the cyst is impossible owing to its situation, or inadvisable owing to infection, it should be laid open, as much of the wall resected as is necessary, and the cyst packed and marsupialized. If anatomical difficulties prevent this, the cyst may be anastomosed with the duodenum. The operative mortality is stated as 12 per cent.

5 Post-operative Hyperpyrexia in Young Children

A. NIELSEN (*Ugeskrift for Laeger*, April 16th, 1931, p. 416) discusses the problem of post-operative hyperpyrexia in young children, illustrating his observations with five cases. When his first case occurred in 1925, ending fatally, he studied the literature of the subject, to find it almost non-existent. Two more fatal cases followed. In all three the children were healthy, and they had been lightly anaesthetized with chloroform or ether for minor operations which had lasted only five to fifteen minutes. They soon recovered consciousness and seemed to be perfectly well, but in the course of two or three hours the temperature began to rise, and in seven, nineteen, and six hours respectively reached 108.5°, 108°, and 107.8°. The pulse became small, rapid, and hardly palpable, the skin was remarkably pale, and the children were flaccid and motionless. This clinical picture, being so uniform in all three cases, suggested a common cause, and Nielsen suspected that it might be an acute disturbance of the heat regulation, with inadequate loss of heat by the skin. Treatment corresponding to this supposition was adopted in the next two cases, the children being immersed in cold water at a temperature of about 63° F. for a couple of minutes or so, and then rubbed, the skin rapidly becoming pink in the process. In both cases the general condition improved quickly with the fall of the temperature, the apparently moribund and blanched children being restored to normal conditions in a few hours, the only abnormality to persist for twelve to twenty-four hours being a pulse of 130–140. The temperature took about a couple of hours after the immersion to fall to normal. Then, in an hour to two and a half hours, it rose again to about 101.8°, returning to normal in the course of the following twelve hours. Nielsen concludes that this condition is not very rare, and that it is often overlooked, the incorrect diagnostic label given to such cases being acute pneumonia or sepsis of unknown origin.

6 Surgical Cure of Hallux Valgus

C. W. PEABODY (*Journ. of Bone and Joint Surg.*, April, 1931, p. 273) considers that, although hallux valgus develops secondarily from a congenital primary metatarsus varus in many instances, yet in most cases the deformity at the big toe joint is the important one. An operative technique has been evolved on the basic principle of a skeletal or structural readjustment, and correction of the deformity, with maximum preservation of the functionally efficient tissues of the joint. The essential points for the successful operative treatment of hallux valgus are the preliminary excision of exostosis, cuneiform or trapezoid resection just proximal to the articular surface, realignment of the joint without sacrifice of any part of it, and reconstruction of mesial collateral ligament. Under local or regional anaesthesia the joint is exposed by a curved dorso-medial incision along the side of the metatarsal, and the superficial layers are dissected back only in this proximal part. Incision in the capsule begins at the edge of the phalanx, it continues around the exostosis on the dorsum of the joint and through the periosteum of the neck of the bone, where it curves mesially nearly to the plantar aspect, and continues back almost to the joint line. The bursa is freed from the exostosis and turned down in the outlined flap, which serves later for the reconstruction of the mesial collateral ligament. This flap is reflected, and the exposed exostosis is excised level with the neck of the bone. A raw bone surface for reimplantation of the capsular ligament is obtained by clearing a thin shaving from the side of the metatarsal neck. A small drill hole is made in the angle between the articular cartilage and the section by which the exostosis was removed; a second hole is placed one inch proximally through the mesial edge of the shaft. A chromic gut suture is passed through the holes and drawn aside. A wedge-shaped resection of bone is made between the holes, but not quite through the opposite cortex. After the wedge has been removed the defect in the bone is closed up by tightening and tying the suture through the drill holes. Peabody recalls 55 cases in which this operation was performed, 106 feet having been operated upon. It was found that bony union occurred in a very short time, convalescence was comfortable, the cosmetic result was perfect, the joint was mobile without loss of power, and there was no evidence of recurrence when properly fitting shoes were worn.

Therapeutics

7 Secondary Therapeutic Action of Bismuth Subnitrate

According to R. BENSAUDE and J. COTTET (*Presse Méd.*, May 9th, 1931, p. 673) the administration of bismuth subnitrate in gastro-intestinal diseases also produces marked amelioration in the frequently associated disorders of the nervous and circulatory systems. Paradigestive troubles may affect either the heart or the arterial system, and may also cause neuro-circulatory disturbances. The etiology of these is discussed, and ten illustrative cases are recorded. When properly administered in daily doses not exceeding 20 grams there is no danger of intoxication, even though the salt continues to be given for a long time. Particular benefit is derived in various forms of headache, migraine, vertigo, and hypertension, most of which, according to the authors, have an intestinal origin.

8 Gold Salts in Lupus Erythematosus

W. U. RUTLEDGE (*Arch. Derm. and Syph.*, May, 1931, p. 874) has been treating lupus erythematosus with three gold preparations—namely, gold sodium thiosulphate, 4-amino-2-aurothiophenol carbonic acid, and sodium auro-thio-benzimidazol carboxylic acid. At first most of the patients were treated entirely with the gold carbonic acid compound, but the other two preparations were used more extensively later. In cases in which toxic reactions developed, or which appeared resistant to one type of preparation, another was employed; in some cases all the three compounds were used. When the carbonic acid salt was first tried the treatment was started with minute doses, which were increased until local reactions appeared, after which there was a cessation of treatment lasting from two to six weeks until the reaction had disappeared. A dose of more than 150 mg. was rarely given at one time, although in one resistant and tolerant case a dose of 150 mg. was employed for six to eight weeks without the development of any untoward reaction other than a few small aphthous ulcers in the mouth. Injections of gold sodium thiosulphate were given once a week, or once a fortnight, in doses ranging from 50 to 500 mg., but there was no evidence that the larger doses were more effective than the smaller ones, though more prone to bring about toxic reactions. In the case of the gold salt of carboxylic acid, the doses, ranging from 50 to 100 mg., were administered once a week. The author considers that all these preparations have a definite value in the treatment of lupus erythematosus, and are superior to any other method so far devised. Of 56 cases, 18 were arrested and 30 were improved. Since

in this condition recurrences may follow an apparent clinical cure, and since five such sequels were observed in his series, he does not feel justified in counting patients as cured who remain free from a return of the condition even for a period of two years after treatment. In no case did cure follow the sole use of the carbonic acid salt, subsequent treatment with gold sodium thiosulphate or carbon dioxide snow being necessary. As a precaution against recurrence he advises eight additional injections of a gold compound during a period of three months following the disappearance of all lesions.

9 General Treatment of Acute Rheumatic Endocarditis

M. J. SHAPIRO (*Minnesota Med.*, May, 1931, p. 428) insists on the necessity of treating for several months in hospital children who show signs of acute rheumatic endocarditis. As the result of studying a group of cases of this kind, he has been impressed by the fact that these children continue to show signs of rheumatic activity for months, and even years, after the acute infection has subsided. In most cases there is chronic daily pyrexia up to 100° F., associated with frequent attacks of pain in the joints and muscles, tachycardia, pallor, fluctuating weight, with constant and progressive changes in the heart condition —a simple mitral regurgitation evolving into mitral stenosis and later aortic regurgitation. Tonsillectomy does not seem to protect the heart from rheumatic fever, or avert subsequent attacks. The only practical form of treatment would, therefore, seem to be rest in bed for some months (at least six), followed by a graduated return to ordinary activity. The author quotes Campbell and Warner, who have reported that under this treatment the number of relapses in the first three years is halved, this being the more remarkable in that the cases were of the more severe types. Special attention has to be paid to nutrition, and ultra-violet therapy is useful.

Laryngology

10 Tracheotomy in Stages

A. HAUTANT (*Ann. d'Oto.-Laryngol.*, February, 1931, p. 136) emphasizes the gravity of the prognosis of tracheotomy in aged and debilitated patients, and especially in those with progressive stenosis of such an extent that asphyxia is imminent. Two cases were observed, however, which before tracheotomy presented small laryngeal fistulae; in the first, following laryngo-fissure, and in the second, due to radium necrosis. In these cases tracheotomy was without incident. These results led the author to elaborate the following techniques of tracheotomy by stages. In cases where asphyxia is imminent an incision is made down to the trachea, and the isthmus of the thyroid is divided, and ligatured. The trachea is incised vertically, and a vertical strip of trachea, one to two millimetres wide, is resected. A silk suture is then introduced through the skin and muscle planes, passed round the neck, and tied to a similar suture from the other side of the incision. The musculo-cutaneous wound is thus kept open, and is lightly packed with sterile gauze. The incision in the trachea is sufficient to relieve the dyspnoea, and the reaction is slight. Four or five days later the tracheotomy tube is placed in position. In cases where tracheotomy is not urgent, the soft tissues are divided down to the trachea, which is not incised until the fourth or fifth day. Four days later a tracheotomy tube is placed in position. By applying this technique it has been possible to operate without any grave reaction in aged and febrile patients.

11 Paralysis of the Dilators of the Larynx

J. REBATTU and J. DECHAUME (*Rev. de Laryngol., d'Otol. et de Rhinol.*, February 15th, 1931, p. 95) review the etiology of bilateral abductor paralysis of the larynx. The condition is seen in tabes dorsalis, typhoid fever, lead poisoning, and other intoxications, and in syringobulbia. It is also found in syphilis apart from tabes dorsalis; in fact, all cases of dilator paralysis for which no other cause can be found should be considered to be of syphilitic origin. These cases give excellent results when treated by energetic antisyphilitic measures. The authors review the various possible anatomical sites of the lesion. A cortical lesion is not entertained, because so vital a function must be situated in the hind-brain. It is difficult to believe that a meningo-vascular lesion could pick out so small an area as only to affect the abductors of the larynx. Though the suggestion of peripheral neuritis is an attractive theory it is negatived by the pathological condition of the cerebro-spinal fluid (increase of lymphocytes). Evidence of a nuclear lesion is still inconclusive, though some experimenters claim to have demonstrated a dilator centre in the formatio reticularis, and distinct from the adductor centre, but the rarity of associated paralyses makes it difficult to accept this theory in the majority of cases. The last theory is that an inflammation of the ependyma of the fourth ventricle affects the dorsal vagus nucleus which lies just subjacent in the floor of the fourth ventricle. One case is described in which a histological examination of the medulla was possible. In this case the striking condition was a very localized perivascular infiltration in the region of the intrabulbar vagal fibres. There was only very little superficial involvement of the ependyma.

12 X-Ray Treatment of Chronic Tonsillitis

O. MAYER (*Wien. klin. Woch.*, April 17th, 1931, p. 521) denies that recurrent tonsillitis and tonsillar abscess are prevented by *x*-ray treatment, which may even cause severe local injury. The changes in the tonsillar tissue after irradiation include the appearance of retention cysts and sepsis, leading to abscess formation. In two patients seen by Mayer after *x*-ray treatment in America the tonsils were shrunken and cirrhotic; they exhibited numerous deep crypts which contained pus and plugs of debris. Both patients had had recurrent tonsillar abcesses since irradiation. On histological examination excessive irregular fibrosis was found with scanty adenoid tissue and deep cystic crypts, filled with pus and debris. In addition, both patients complained of severe dryness of the pharynx; the pathological appearance suggested xerosis in one case. The explanation of this very disastrous sequel is that the salivary glands were irradiated simultaneously with the tonsils; thus a parotid fistula may be induced to heal by arresting the secretion of saliva by *x* rays. Not only the parotids but also the other salivary glands were apparently rendered atrophic. Mayer remarks that irradiation of the tonsillar regions may involve large vessels and nerves as well as the cervical ganglia, resulting sooner or later in trophic changes. In both of his patients, tonsillectomy was rendered particularly difficult, not only by the small cirrhotic tonsils being so closely adherent to surrounding tissues, but also owing to the fact that severe haemorrhage occurred, requiring surgical intervention. Irradiation may retard the healing of a chronic tonsillitis, by partially obliterating the crypts, and by inducing other severe lesions.

Obstetrics and Gynaecology

13 Treatment of Occipito-Posterior Cases

A. TAYLOR (*Journ. Obstet. and Gynaecol. of the British Empire*, Spring, 1931, p. 85) pleads for a more conservative treatment of the occipito-posterior position. He asserts that dystocia is in the main confined to the group of cases in which the head is fixed in the pelvis, having entered the brim as an occipito-posterior late in pregnancy; there may be superadded an excessive obesity or a funnel-shaped pelvis. This group of cases is elusive, owing to the apparent depth of the head early during labour. For its detection the third grip is important, and a general anaesthetic is often required, but a clue to the existence of a funnel-shaped pelvis may be given by the discovery of an unduly small distance between the ischial tuberosities. After the onset of labour, therapeutic

correction from above is prevented by the control exercised by the brim on the head, and from below by the cervix; the cases must therefore continue in the occipito-sacral position, and progress is inevitably slow in primiparae. Such cases remain brim-controlled and brim-adapted for some time after the head has come into contact with the pelvic floor. It is at this juncture that the writer recommends watchful expectancy, and the administration of sedatives, rather than attempts to correct manually by the combined method, or by forceps. Bimanual examination under general anaesthesia is invaluable when the cervix is fully lifted over the head, but the latter is not showing at the vulva; successful delivery by forceps is to be expected where the head can be pushed down until no longer palpable above the brim. If the conditions for forceps application are not fulfilled Caesarean section must be seriously considered. Version, though preferable to manual rotation, is inferior to forceps application, and jeopardizes foetal life. Taylor is sceptical as to the efficacy of bolster-case and binder applications in correcting the occipito-posterior position.

14 Chronic Ulceration of the Vulva

P. P. JOSSERAN (*Thèse de Paris*, 1931, No. 115), who records eight illustrative cases in women, aged from 22 to 62, states that in addition to the well-recognized ulceration caused by syphilis, gonorrhoea, soft chancre, mycosis, tuberculosis, and cancer, prostitutes may develop a simple chronic ulceration of the vulva as the result of repeated coitus. Removal of this cause is sufficient to produce a cure. In elderly women, however, the ulcers, instead of showing normal cicatrization, undergo a fibrous and protracted organization, which is not modified by rest or local treatment.

15 Retention of the Dead Foetus in the Uterus

B. BINEL (*Riv. d'Ostet. e Ginecol. Prat.*, February, 1931, p. 69) believes that the occasional retention in the uterus of a dead foetus after expected term, although less common than in ectopic gestation, is not excessively rare; the literature contains references to retentions lasting so long as thirty or forty years. The signs of foetal death during the first half of pregnancy are malaise, slight pyrexia, nausea, and vomiting; the appearance of varices, lactation, diminution or arrest of the growth of the uterus; and acetonuria. During the second half, cessation of the foetal movements and of the heart beat may also be made out, and radiography may show Spalding's sign of overriding of the cranial bones. When the patient is first seen a considerable time after death of the foetus, signs not only of that event, but also of pregnancy, may be obscure. The uterus assumes the characters of a soft doughy tumour, and the softening of the cervix is diminished. Diagnosis is helped by detection of the uterine contractions, and occasionally by the finding of crepitus. A case is described in which a 3-para, aged 37, expelled by the vagina foetal bones fourteen months after the conception of a child that died during the sixth month.

16 Corpus Luteum Cysts and Amenorrhoea

G. COTTE (*La Gynécol.*, March, 1931, p. 129) records three cases of married women in the fourth decennium who were operated on for supposed early unruptured ectopic pregnancy. After a few weeks' amenorrhoea the patients had felt themselves pregnant; colostrum was noted, and examination showed, in addition to some uterine enlargement, a small cystic adnexal swelling which revealed itself at operation as a corpus luteum cyst. In addition, two cases are described in which ectopic pregnancy was suspected and a cystic adnexal swelling was detected; expectant treatment led to disappearance of the cyst, with return of the menses. In the first cases resection of the cyst was speedily followed by menstruation. Ablation or rupture of a corpus luteum cyst has previously been noted by Zondek and others as preceding a menstrual flow. Physiologically the coexistence of amenorrhoea and a lutein cyst is explained by the persistence in the endometrium of a pregravid phase under the hormonic influence of lutein. Why the corpus luteum cyst should persist is less clear; an occult pregnancy has been postulated (such could be excluded in Cotte's cases), but an anterior hypophyseal disturbance of function is more probable. It is certain that not all corpus luteum cysts are accompanied by amenorrhoea.

Pathology

17 Experimental Production of Scarlet Fever

T. TOYODA, Y. FUTAGI, and M. OKAMOTO (*Journ. Infect. Dis.*, April, 1931, p. 350) claim to have produced scarlet fever by throat inoculation with pure cultures of haemolytic streptococci. Two strains were used, both isolated from the throats of scarlet fever patients; at the time of inoculation they were in the third and fourth generation cultures respectively. The organisms were grown for twenty hours on an agar slope and in dextrose broth; a suspension was made; a sterile cotton swab was dipped in the suspension, and then rubbed over the throat. Three boys, apparently between the ages of 3 and 7 years, were used as volunteers; they were all Dick-positive. The time of the experiment was early winter. There had been no contact with scarlet fever for a long time. The three subjects reacted positively; the temperature rose on the second or third day after inoculation, and a rash came out on the third or fourth day, persisting for two or three days. The throat was hyperaemic and the tonsils slightly enlarged; in two of the subjects desquamation subsequently occurred. In each case the Schultz-Charlton reaction was positive, and after the attack the patient's serum became capable of producing a positive Schultz-Charlton reaction, though before inoculation the serum had been negative. Five subjects inoculated in the summer with an old strain of haemolytic streptococcus, of comparatively low virulence to mice, failed to react. Moreover, children inoculated, apparently during the winter, with filtrates of freshly isolated strains, likewise failed to react. The authors conclude that scarlet fever is caused by the haemolytic streptococcus itself, and not by any filterable body attached to it.

18 Blood Changes in Typhoid Fever

A. M. BONANNO (*Arch. di Pat. e Clin. Med.*, February, 1931, p. 341), from the study of 29 patients suffering from typhoid fever, has observed that in almost every case the blood platelets were diminished in number, the thrombopenia being more marked at the height of the illness, but returning slowly during convalescence to the normal figure. In most cases the platelet count was about 150,000 during the second week, but in one instance only 40,000 was recorded. In nine cases the coagulation time was prolonged, and in two there was retardation of clot retraction. The haemorrhagic manifestations occurring during typhoid infection, especially intestinal haemorrhage, should be attributed chiefly to the anatomical changes which determine the disease; these are favoured also by the special haemoplastic condition resulting from the infection itself in the patient, exaggerated in those cases in which a constitutional haemorrhagic diathesis is already present.

19 The Virulence of B.C.G.

J. VALTIS and F. VAN DEINSE (*C. R. Soc. de Biologie*, April 24th, 1931, p. 1109) refer to the demonstration by Valtis and Saenz that the inoculation with large doses of B.C.G. of animals previously injected with tubercle bacilli, as also the introduction of tuberculous filtrates into animals previously injected with B.C.G., does not increase the virulence of the latter. Another series of experiments, here described, was undertaken to determine whether culturing B.C.G. on tuberculous filtrates would increase its virulence; no such intensification was detected. According to the authors the results of these two series of experiments prove that prophylactic treatment with B.C.G. is entirely innocuous, even in the case of the newborn of tuberculous mothers.

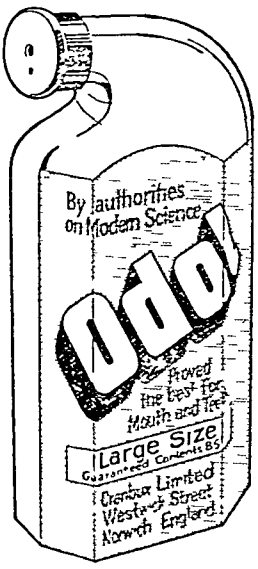
What three doctors say about Odol

1. STOMATITIS

"I have often recommended Odol to patients suffering from Stomatitis and have found it very efficacious."

....., M.R.C.S. Eng., L.R.C.P. Lond.

2. NOSE WORK



"I use a solution of Odol for all nose work, washing out the antrum and sinuses, etc. It is excellent and a soothing antiseptic."

....., M.D.

3. ZYMOTIC DISEASES

"It is most excellent in septic conditions of the mouth such as one finds in the zymotic diseases."

....., M.C., L.R.C.P., M.D.H.

Not only is Odol definitely antiseptic—not only does it destroy disease germs of the mouth and throat—not only does it check the growth of bacteria for hours after use—but it is perfectly safe. Non-toxic, non-caustic, Odol does not injure the teeth or the mucous membrane of the mouth.

Samples and literature will gladly be sent to any member of the Medical Profession on application to:

CRANBUX LIMITED OF NORWICH

BRITISH MADE BY BRITISH LABOUR
FINANCED BY BRITISH CAPITAL

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

2"	2½"	3"	
1/7	1/9	2/-	EACH

When stretched measure six yards (approximately).

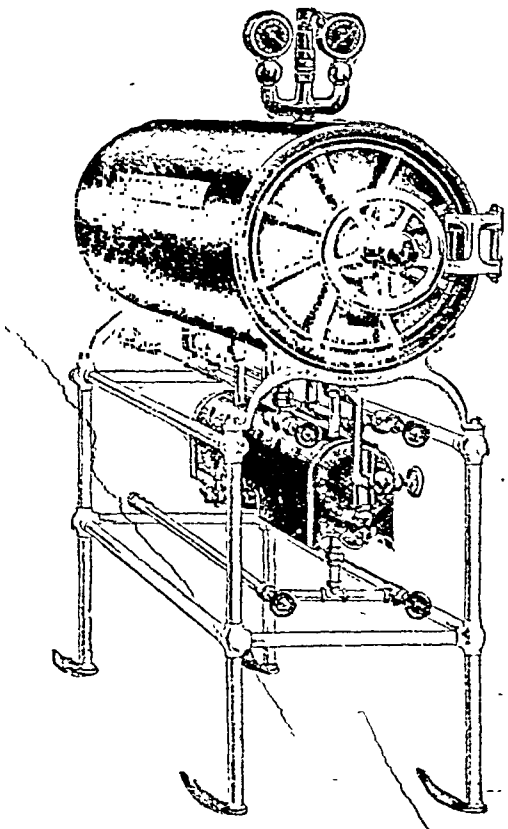
SAMPLE 3 in. "VARIBAN" ELASTIC PLASTER BANDAGE sent POST FREE on receipt of P.O. for 2/3.

"CELLANBAND"

PASTE BANDAGES

in the Treatment of VARICOSE ULCERATION, PHLEBITIS, etc.

MESSRS. CUXSON, GERRARD & CO. Ltd. have pleasure in informing the members of the medical profession that they are now manufacturing Paste Bandages—under the descriptive name of "Cellanband"—strictly according to the formula mentioned in the article quoted below.



"The paste-bandage constitutes a definite improvement upon the methods so far available, both in convenience of application and in the results obtained."
(Vide article on page 560, "B.M.J.," Oct. 4th, 1930.)

SAMPLE BANDAGE 1/- Post Free

Descriptive literature available on request.

Sole Manufacturers:

Distributors to the Medical Profession:
The MEDICAL SUPPLY ASSOCIATION Ltd.
167-185, Gray's Inn Road, LONDON, W.C.1. 10-13, Teviot Place, EDINBURGH. 6-12, Holly St., SHEFFIELD.

HIGH-PRESSURE
STERILIZERS
(Arnold & Sons Patent)
STEAM and VACUUM
Improved Models

Modern STERILIZER EQUIPMENT by ARNOLD & SONS

"SS Empress of Britain"
The entire sterilizing plant, which is of most modern design, was supplied by ARNOLD & SONS, LONDON

Models in various sizes for heating by ELECTRICITY, GAS, or STEAM.

Finished in the following— CHROMIUM, NICKEL, DULL MATT.

Prices and full particulars on application.

Arnold & Sons (JOHN BELL & CROYDEN)

Makers of Superior Hospital Furniture and Stainless Steel Instruments,

50-52, Wigmore Street, London, W.1

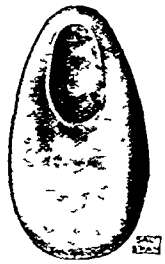
Telephone: WELBECK 5555. (12 lines).
Telegrams: INSTRUMENTS, WESDO, LONDON.

SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply"

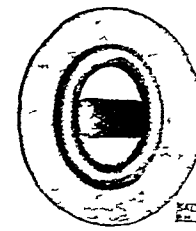


Salt and Son Ltd

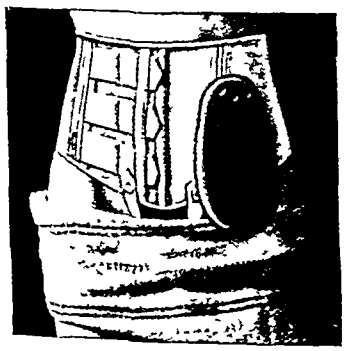
Showing attachment of receiver and bag to belt.

SALT'S (PATENT) COLOSTOMY BELT
EMBODIES THESE VITAL POINTS

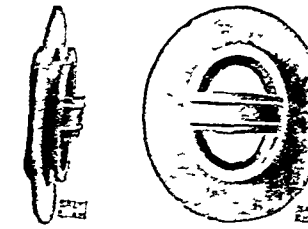
1. Moulded Indiarubber Receiver, sterilizable by boiling.
2. Mouth of Bag kept open for free entry of Faeces.
3. Easy removal and cleaning of Bag without removal of Belt.
4. No crevices to hold Faeces and therefore little odour.
5. Less bulky and more sanitary than any other.
6. Rubber portions far more durable than in the old style Belt.



Indiarubber bag which can be detached at will for cleaning.



This belt can also be provided with special cup instead of bag.



Showing bag attached to receiver.

Showing rubber receiver with pad fitting next to body and rubber flange to prevent belt becoming soiled.

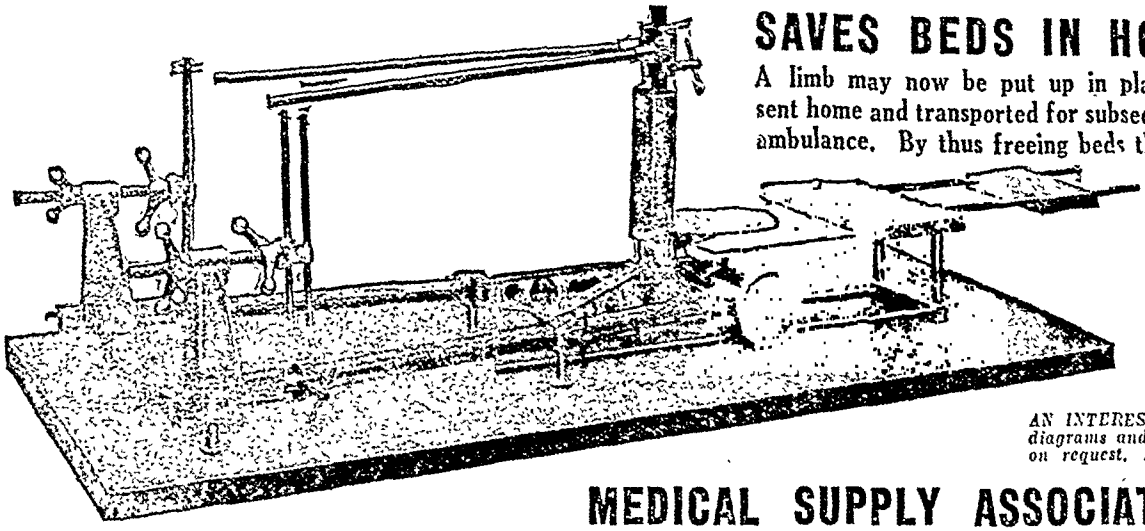
Full particulars on request.

Showing other views of receiver See groove over which aperture in bag is stretched and curved bridge to hold open mouth of bag

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT

ESTABLISHED 1793



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

DEAF DOCTORS

AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me";* without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under *guarantee.*

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

MEMBER'S STATEMENT:

Harley Street, W.1.

Dear Mr. Watson,

I beg to acknowledge receipt of your cheque value £68 4s. 6d. I wish to thank you most heartily for obtaining the amount for me, which, in all probability, without your active interest would have been an entire loss.

I have spoken most heartily of your accomplishment to several of my colleagues and I sincerely hope they will put some work in your way. You have entirely satisfied me.

The Goodness of Turkish Cigarettes

When the doctor says —"Smoke fewer cigarettes!" patients reply sweetly "All right, I'll smoke more Royal Beauties!" and the doctors are not cross—they understand, for pure Turkish contains only about half the nicotine of ordinary Virginia tobacco and is therefore much better for you And the linen filters in Royal Beauties do the rest. Some people favour Turkish tobacco is doped Royal Beauties are unconditionally guaranteed to contain nothing but absolutely pure undoped Turkish tobacco—so that's that

In three sizes Turkish, 9/6, 10/6 and 12/6 a hundred

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE

(FORMERLY DUFF HOUSE, BANFF)

It also contains Laboratories for biochemical, research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

VICHY FRANCE

Renowned for Treatment of GOUT, DIABETES, and OBESITY.

The waters of Vichy belong to the sodium bicarbonate group. They are generally gaseous, clear, and colourless. They are nearly all similar in composition and contain, approximately, a total of 7.5 grammes of mineral matter which includes, notably, bicarbonates of sodium, potassium, calcium chloride and sulphate of sodium, free carbonic acid, and those rare gases: argon, krypton, xenon, helium, neon, etc. At their source, the springs present differences in temperature which give a variety of physiological actions due to their peculiar vitality.

The Thermal Establishment is justly considered as a model of its kind, and every care is taken that the latest discoveries in physiotherapy may be utilised under the best possible conditions for allowing the specific action of the waters to give the most beneficial results.

The cost of a stay at Vichy is surprisingly moderate. Hotels are numerous and comfortable and range from the most luxurious to the modest pension.

Detailed information concerning the treatment at Vichy may be had by addressing the Compagnie Fermière de Vichy, 24, Boulevard des Capucines, Paris.

Full Schedule of Terms and Conditions will be forwarded on application.

WE MODERNS PREFER

electric lights  to old oil lamps

 and motor cars  to the

horse and gig  of an earlier

age  because we get results

more quickly and more efficiently.

Similarly in constipation — a modern day has developed a modern way — AGAROL. To meet every modern need, this product combines efficiency with palatability. No oily taste, no artificial flavouring to get used to.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Effectiveness must be experienced.
A supply gladly sent for trial.

AGAROL *for Constipation*

BRAND COMPOUND

FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists since 1856.*

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

PERCAINE "CIBA"

Trade Mark Registered

The New Local Anæsthetic for Regional, Infiltration, Surface and Spinal Anæsthesia

Acts in extreme dilution (0·5—2 : 1000).
Produces anæsthesia of unattained intensity and duration.
Not a narcotic. Economical in use.
Belongs chemically to a class entirely different from cocaine and its derivatives.

Vide *British Medical Journal*, March 15, 1930, pp. 488-9, and 495-6, and April 5, 1930, pp. 669-70. *The Lancet*, March 15, 1930, pp. 573-4 and 587. *British Journal of Anæsthesia*, April & July, 1930. *Proceedings of the Royal Society of Medicine*, May, 1930, pp. 919-928. *British Journal of Urology*, June, 1930, pp. 129, 130 and 179.

Hemoplastin

(P., D. & Co.)

A Physiological Blood Coagulant, Biologically Assayed.

HEMOPLASTIN is a sterile serum derivative containing in solution those physiological agents believed to be responsible for the formation of the blood clot. It is intended for use in the control of haemorrhage due to defective coagulability of the blood, and is suitable for either parenteral or oral administration.

Before it is released from the laboratories for general distribution, Hemoplastin is subjected to biological tests which demonstrate its ability to reduce the coagulation time of dog's blood. The standard required of Hemoplastin is that an injection of 2 c.c. shall, within the space of two hours, reduce the coagulation time to one-third of its normal value.

Indications.

Hemoplastin is indicated for the prophylaxis and control of haemorrhage incidental to surgical operations or associated with haemophilia, purpura, etc. Although normally it is administered hypodermically in doses of 2 c.c.—or 5 c.c. in severe cases—it has been shown to be effective if given by the oral route in doses of 5 c.c.

Hemoplastin is supplied in bulbs of 2 c.c. and 5 c.c.
Hemoplastin (Oral) is supplied in bulbs of 5 c.c.

FELAMINE BRAND SANDOZ

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-

SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.

5, WIGMORE STREET, LONDON. W. 1.

FURUNCULOSIS

Whether there be a single boil or a multiplicity of furuncles, subcutaneous injections of EDWENIL will produce a prompt response.

If treated in the early stages, the boil or furuncle disappears without coming to maturity. In more mature lesions the growths quickly come to a head, burst, and there follows a rapid recovery.

The time required for the complete resolving of even an extensive carbuncle is interestingly short.

FOR PROMPT RESULTS IN COLDS AND HAY FEVER USE EDWENIL—

A POLYVALENT ANTIBODY.

Obtainable in 25 and 12½ c.c. Bottles.

MADE ONLY IN THE LABORATORY OF

E. H. SPICER & CO., LTD.,

WATFORD, HERTS.

Telephones: WATFORD 5281-5285.

LEWIS'S—1844-1931

Messrs. H. K. Lewis and Co. Ltd. have pleasure in announcing that the rebuilding and equipment of their premises is completed. During the progress of the work every effort was made to maintain the regularity and efficiency of the services, and while hoping that no one suffered serious inconvenience, the Directors would like to express their appreciation of the consideration shown.

An illustrated booklet has been prepared describing the new building, the establishment and growth of the business, and the present services the Company offers. A copy will be sent on request to anyone who may not already have seen it.

To Members of the British Medical Association passing through London to or from the Eastbourne Meeting a cordial invitation is extended to visit and inspect the new premises, which occupy the old site at the corner of Gower Street and Gower Place.

THE METABOLISM OF TUMOURS

Investigations from the Kaiser-Wilhelm Institute for Biology, Berlin-Dahlem

Edited by

OTTO WARBURG

Edinburgh Medical Journal:—"The work of Warburg stands out as a definite landmark in the progress towards the final solution of the main problem of the cause and mechanism of the development of malignant disease. This volume contains the careful and complete record of his work, and should be studied not only by the biochemist, but by all who ponder over the problems of cancer."

A New Departure
in Cigarette Manufacture

du Maurier
VIRGINIA

with the exclusive filter-tip

The Ministry of Health (Memorandum to Local Authorities, 8th Series). "No evidence has been adduced to support the contention that the mere inhalation and exhalation of tobacco smoke is of importance, although two possible causes of 'irritation' are *heat* and the *products of combustion.*"

The Claims of the Manufacturer

I. The filter-tip is selective in its action and while permitting the full passage of all the desirable constituents, shows a high capacity for retaining both the pyridine bases and non volatile bodies, which undoubtedly form the principal source of throat irritation.

II. Unfiltered smoke is as dangerous as unfiltered water and as irritating as dust-laden air. The filter-tip effectively purifies tobacco smoke from harmful irritant and acrid substances which are inevitably formed when tobacco leaf, even of the finest quality, is burned.

III. By the introduction of the filter-tip the palate loses nothing, but the voice and throat gain immeasurably as the irritants are held in check without impairing the flavour or delicate character of the smoke. This is the central advantage to be gained from the filter-tip

IV. Cigarettes containing this filter-tip will be welcomed both by the medical profession and the public as a valuable means of preventing "smoker's cough" and other adverse effects on the pharynx, larynx or general health, traceable either directly or indirectly to the irritants and acrids in tobacco smoke.

V. They constitute the only safe form of smoking for those predisposed to, or suffering from, pharyngitis, laryngitis, or any form of bronchial or respiratory affection They are invaluable in cases of gastric trouble due to tobacco tar.

A Selection from many Authoritative Endorsements

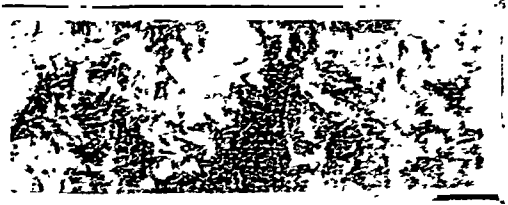
The aim of *this ingenious filter* is to trap the irritating pyridine derivatives and other non-volatile bodies, while permitting free passage of the agreeable volatile constituents of tobacco smoke.

The British Medical Journal, April 18th, 1931. p. 692.

A filter-tip must not only be efficient as a filter to irritating and noxious products, but must not affect the flavour . . . pyridine, the most offensive constituent of tobacco smoke, and other non-volatile irritant substances are retained by the ingenious filter-tip which is used in du Maurier cigarettes. From a personal trial we can testify to the *pleasant flavour and aroma* and to the *distinct lack of irritation* experienced in smoking these cigarettes.

The Practitioner, May, 1931. p. 584.

We have tested these cigarettes and find them to be *cooler* and *less irritating* to the mucous membrane than ordinary cigarettes of good quality without the filter-tip.

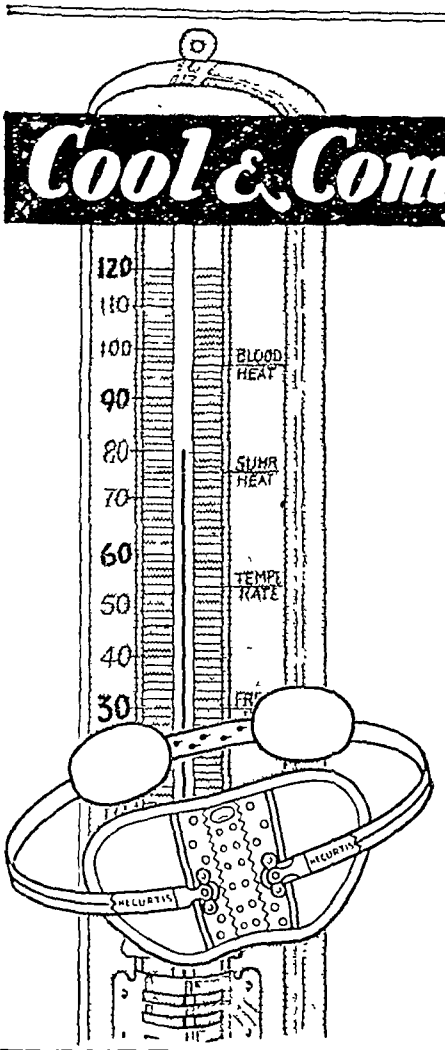


The filter-tip . . . retains bodies which are generally held to be the principal cause of throat irritation. Additional advantages of the filter-tip comprise *protection of the lips, teeth and fingers from unsightly stain,* and prevention of fragments of tobacco from getting into the mouth.

The du Maurier cigarettes may be regarded in every way as satisfactory, and they constitute a distinct and hygienic advance in the marketing of cigarettes.

The Lancet, January 24th, 1931. p. 194.

Magnified view of cellulose fibre (contained in the filter-tip). BEFORE SMOKING.



Magnified view of cellulose fibre (contained in the filter-tip). AFTER SMOKING.

'du Maurier' Virginia Cigarettes at 20 for 1/-, 50 for 2/6, can be obtained from Peter Jackson, 217, Piccadilly, London, W.1, but we would prefer you to buy them from your tobacconist.

OVALTINE

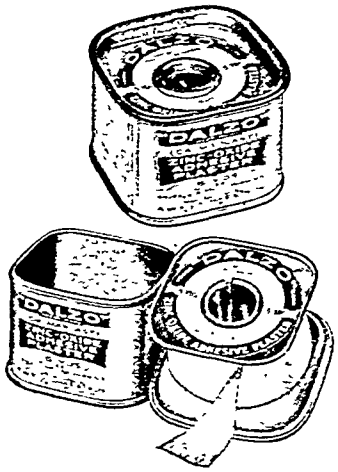
IN NEURASTHENIA.

Every potential neurasthenic is greatly assisted by liberal drinking of "Ovaltine." It is recommended as a between meals beverage or as a mid-day "light lunch," and it displaces tea or coffee with complete advantage.

"Ovaltine" is also invaluable when taken at the hour of sleep. Its use in this way has often avoided the need for employing hypnotic drugs.

The value of "Ovaltine" has been proved many times in such cases. It provides nourishment of the right kind, and in a form readily dealt with by the impaired digestive organs. "Ovaltine" permits of the liberal ingestion of food without taxing the digestive power.

"Ovaltine" is a complete natural food, yielding in one cupful a greater food value than three eggs. This delicious beverage is unquestionably a tonic nerve nutrient of a high order.



A liberal supply for clinical trial sent free on request.

A. WANDER, Ltd., 184, Queen's Gate, S.W.7.

"DALZO"

THE GUARANTEED SELF-ADHESIVE ZINC-OXIDE PLASTER

British Made, with British Capital, by British Workmen, for British Doctors.

- Airtight
- Dust-proof
- Damp-proof
- Guaranteed for two years
- Plaster keeps clean
- Easy to remove and replace spool quickly
- Original non-rolling spool

Supplied in all widths, ½ to 3 inches, on 5 and 10 yard spools.

LEICESTER. LONDON. DUBLIN. LEEDS. BRADFORD.

The Diagnosis of Partial Vitamin B Deficiency

A deficiency of Vitamin B not amounting to complete deprivation is more common than is generally supposed.

The condition is due to a progressive deterioration of the intestinal muscular and nervous system, resulting in general malnutrition in all its characteristic forms.

A correction of the dietary by the addition of a suitable quantity of Bemax very quickly results in a marked improvement.

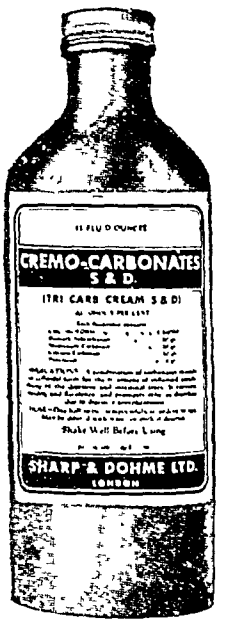
Healthy digestion is restored, the appetite improves, easy elimination is secured and the nervous symptoms subside.

Medical men have testified to the remarkable tonic and recuperative effects of Bemax in all cases of Dyspepsia, Constipation, Sleeplessness, Nervous Debility, Rheumatism and all Vitamin B deficiency diseases. It is invaluable food for growing children.

Try Bemax for supplemental B vitamin feeding. It is entire cereal embryo, thoroughly stabilised against deterioration and standardised as to vitamin B content. It assays at least 560 units per ounce (Sherman method) probably the richest known source.

Laboratory Reports on Bemax and Clinical Sample for personal trial will be sent to any Medical Man on request.

BEMAX



THE NATURAL VITAMIN TONIC FOOD

THE BEMAX LABORATORIES, 23, UPPER MALL, LONDON, W.6.

CREMO CARBONATES

is pre-eminent as an Antacid

- Prepared in colloidal form.
- Increased surface area due to highly dispersed state of the active ingredients.
- Correspondingly greater acid-neutralizing power.
- Harmless in large doses.
- Does not disturb the acid-base balance of the blood and body fluids.
- There is no secondary acid rise nor ill after-effect.
- It does not constipate.
- It has no salt or earthy taste.

Cremo-Carbonates, S & D, is used with excellent results in all cases of digestive disorders accompanied by excessive acidity.

The Endocrine Glands

NOW a complete range of single gland products

Here is a new full list of the entire range of Reed & Carnrick's single gland products, supplied in tablets (uncoated or enteric coated) and powder form :—

Corpus Luteum
Mammary
Pancreas (Coated only)
Parathyroid
Pineal
Pituitary Anterior
Pituitary Posterior
Pituitary Whole
Suprarenal Cortex
Suprarenal Medulla
Suprarenal Whole
Thymus
Thyroid ("Thyracoids")

Packings : Tablets 100. Standardised Strength. Powder 1 oz. bottles.

Descriptive literature from Sole Distributing Agents for U.K. and Irish Free State :—

COATES & COOPER, LTD.,
41, Great Tower Street, London, E.C.3.

SINGLE GLAND PRODUCTS

Manufactured by REED & CARNRICK, Pioneers in Endocrine Therapy, Jersey City, NEW JERSEY.

HORLICK'S MALTED MILK

possesses characteristics which make it especially valuable as a diet for surgical cases. Some nutritional disturbance is inseparable from surgical operations, but this can be minimized if due regard be paid to the pre-operative diet. It has been shown that surgical patients make better progress if their glycogen stores are adequately maintained, and for this purpose foods with an ample proportion of easily assimilated carbohydrate are more valuable than protein foods. HORLICK'S has a mixed content of lactose, maltose and dextrin, and the value of maltose where high sugar feeding is indicated is well known. With a considerable number of patients the very idea of an operation results in lack of appetite. Because of its delicate and appealing aroma, HORLICK'S overcomes the distaste for food, and ensures that the patient can be fed to within a reasonable time of the operation. The carbohydrate reserves are thus adequately maintained; the toxicity due to anaesthesia is lessened; the risk of post-operative vomiting reduced; and recovery materially assisted by the increased comfort and well-being of the patient.

"THESE RESULTS ARE OF FAR-REACHING IMPORTANCE AND OPEN UP A WIDE FIELD FOR THE EMPLOYMENT OF DIMOL IN COLONIC IRRIGATION."

Vide The British Journal of Physical Medicine, May, 1931, pp. 32-33.

"Colonic irrigation was administered to two separate patients, ONE being treated with Dimol Lavage Powder in the douche.

The OTHER (the control) being treated with a slightly hypotonic saline solution only." The results were as follows:—

Specimen	*With Dimol Solution.*		*Without Dimol Solution.*	
	Bacteria per c.c.	*B. coli per c.c.*	*Bacteria per c.c.*	*B. coli per c.c.*
15 minutes	*5*	*0*	*More than 2,000*	*50*
20 ,,	*3*	*0*	*do.*	*More than 2,000*
30 ,,	*2*	*0*	*do.*	*1,000*

The addition of Dimol Lavage Powder to the fluid injected provides a highly potent bactericide for the purpose of destroying any micro-organisms not removed by the mere mechanical action of the wash and is "an outstanding advance in Colonic Therapy." A full reprint of the article which appeared in the "Journal of Physical Medicine" will be sent on application.

BOOTS PRODUCTS
ARE OBTAINABLE THROUGH ALL
BRANCHES of BOOTS The CHEMISTS

ACRIFLAVINE (BOOTS)

ONE of the most potent of modern antiseptics, physiologically pure and extremely soluble in water. ACRIFLAVINE (BOOTS) kills organisms in a concentration of 1 in 100,000. Its potency is actually increased in contact with serum. Now recognised as the routine preparation for irrigations in the treatment of Gonorrhœa. Ideal for suppurating wounds and all septic conditions.

Supplied in 5 gm. and 20 gm. bottles, and in Solution Tablets for external use (gr. 1.75 and gr. 2.187).

NEUTRAL-ACRIFLAVINE (BOOTS)

Is specially prepared for internal use (per os) in the form of enteric-coated tablets.

Supplied in 5 gm. and 20 gm. bottles; in Solution Tablets for external use (gr. 1.75), and in enteric-coated tablets (gr. ½) for internal use (per os).

"Eucortone"

(Cortical Extract of Suprarenal)

In the treatment of

Addison's Disease

Efficacy established by biological tests and clinical use

(*Journal of Physiology*, June 6, 1931: *Proc. Physiol. Soc.* May 2, pp. 4, 5, and 9)

"Eucortone" is prepared by the method of Swingle and Pfiffner, and is highly successful in the treatment of Addison's Disease. Particularly striking is the rapid restoration of appetite, weight, strength, and feeling of well-being. Biological tests and clinical use show that "Eucortone" contains the long-sought cortical hormone in an active state and is free from adrenalin activity. The extract contains no irritant or toxic substance, and is sterile.

1 c.cm. is equivalent to 30 grams of cortex. In rubber capped bottles of 25 c.cm.

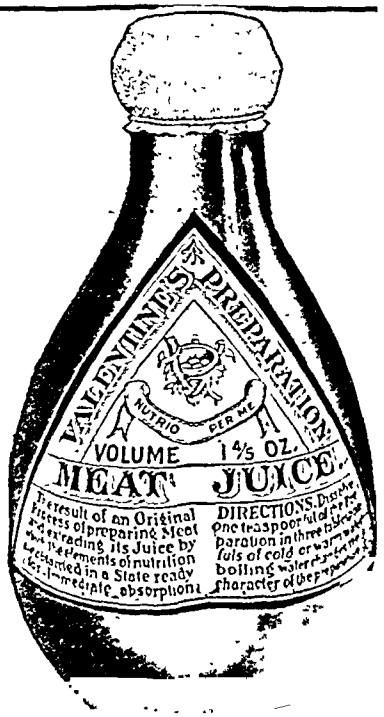
EXTRACTUM GASTRICUM

An aqueous-acid-glycerin extract of the entire mucosa of the fresh stomach, including the pyloric.

Containing the peptic enzymes—proteolytic and milk curdling, the activated principles and naturally associated soluble organic and inorganic constituents. It is a stable, potent fluid, free from alcohol and free from sugar, with an acidity approximately of 0.25% absolute hydrochloric acid, loosely bound to protein, and 25% pure glycerin.

The usual dose is one to two teaspoonfuls, diluted with a little cold water.



Extractum Gastricum is put up in 6-ounce unlettered bottles without literature.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK, and 65, Holborn Viaduct, LONDON, E.C.1.

Agents:

IN Typhoid and other Fevers, Extreme Exhaustion, Critical Conditions, Before and After Surgical Operations, when Other Food Fails to be Retained, Valentine's Meat-Juice demonstrates its Ease of Assimilation and Power to Restore and Strengthen.

Clinical Reports from Hospitals and General Practitioners of Europe and America posted on application.

For sale by European and American Chemists and Druggists.

Valentine's Meat-Juice Co., Richmond, Vir., U.S.A.

The Treatment of Varicose Veins

Although the treatment of varicose veins by injection is a comparatively recent innovation, it is already adopted as the standard procedure.

The solution injected must be non-toxic and, whilst it should produce as little pain as possible, it must necessarily be sufficiently irritating to cause the desired endothelial damage.

Sodium Morrhuate B.D.H. solution meets these requirements completely; it is absolutely non-toxic even in large doses, and injections with it are not only painless, but they do not involve risk of periphlebitis or necrosis.

The technique of administration is simple—one injection, as a rule, being sufficient, although several injections from the upper part of the vein downwards may be made with perfect safety.

Sodium Morrhuate B.D.H. is issued in ampoules in a 5 per cent., or a 10 per cent., sterile solution.

SODIUM MORRHUATE B.D.H.

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURE.

Typical Case.

B K M, aged 12 years.

Diagnosis: Fracture of the right radius and ulna.

Operation: Reduction of fracture—closed method

Anaesthesia: Transverse infiltration block, 40 c c of 1 per cent Novocain-Adrenaline solution being used

Operation: A transverse block was immediately made at a point 5 cm above the line of fracture The fractures were reduced, a moulded plaster splint was applied, and the boy allowed to return home with his mother

Note.—This case is mentioned to illustrate certain points. The child's mother was a widow without funds The child came to the surgery during usual hours on a busy afternoon The necessity for preparing him for General Anaesthesia, as well as the necessity for employing an anaesthetist or sending the child to the hospital—the amount of time required in order to carry out the necessary treatment—were factors which entered into the handling of the case Under the plan mentioned above, an assistant anaesthetised the arm, the surgeon reduced the fracture and the assistant then applied the necessary dressing The total expenditure of time by the surgeon was less than five minutes Furthermore, the child left the surgery travelling on his own power. From an economic standpoint the use of Local Anaesthesia in such a case presents many advantages.

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W C 1)

THE SAFEST LOCAL ANAESTHETIC.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

A British Medical Association Lecture

ON

THE SIGNIFICANCE OF A RAISED BLOOD PRESSURE*

BY

JOHN HAY, M.D., F.R.C.P.

PROFESSOR OF MEDICINE, LIVERPOOL UNIVERSITY; SENIOR PHYSICIAN AND PHYSICIAN IN CHARGE OF HEART DEPARTMENT, ROYAL INFIRMARY, LIVERPOOL

My subject is one of very general interest and also of considerable practical importance, if for no other reason than that a large number of our patients at or over middle age present a raised blood pressure. No one can now afford to be indifferent to the problems associated with variations in blood pressure, for a high pressure is an abnormality which always demands investigation, supervision, and careful treatment. There is a danger that patients may take the variations in their blood pressure too seriously, and it is well to remember that the blood pressure is only one factor in the circulation, and that it must be carefully correlated with the other physical signs and symptoms manifested.

An abnormally high blood pressure indicates some underlying psychological or pathological abnormality, and an attempt should always be made to interpret it in terms of pathology, and finally in terms of prognosis.

The blood pressure, constantly fluctuating within certain limits, rising and falling to meet the changing needs of life, is the resultant of several factors. There are the frequency of and the vigour of the ventricular systole, the distension of the arteries which grasp the blood, and a varying peripheral resistance. More prone to develop in middle age, high blood pressure is not infrequently encountered in the young; it is helpful, therefore, to classify the patients into a few groups.

The Type of Patient

High blood pressure may be latent, causing no symptoms and discovered accidentally in a patient otherwise healthy.

Then there is the thin, spare, sallow, highly strung individual, often nervous, active, and self-opinionated—a neurasthenic with a tendency to constipation and a coated tongue. As a contrast there is the sthenic type: florid, stoutish, muscular, with a vigorous mentality, great driving power, an excellent appetite, a good digestion, and a clean tongue—the man who takes it as a personal affront when he is loaded or refused for life assurance. And, finally, there is the menopausal group, in which the chief etiological factor is probably a dyscrinism, characterized by vasomotor instability, an increase in weight, and obesity hard to dispel; in this group there is a steady increase in the blood pressure, which may slowly subside in the late fifties.

Method of Estimation

The reading of the blood pressure should be taken without fuss and as casually and unobtrusively as possible, and no unnecessary importance attached to the actual recording, and as little as possible said about the findings to the patient. To take a blood pressure reading is simple enough, but my impression is that in some instances the technique is not satisfactory, and the records, especially of the diastolic pressure, are unreliable. This is unfortunate, because the diastolic pressure is of undoubted clinical importance.

*Delivered at Bradford, February 25th, 1931.

The Diastolic Pressure

In Great Britain the diastolic pressure is usually taken as that point at which there is a sudden marked diminution in the intensity of the sounds on auscultation of the brachial artery—normally about 70 to 80 mm. Hg. An increase in diastolic pressure signifies that with each systole a greater expenditure of energy is required to force open the aortic valves. The permanent load on the heart and arteries is greater than normal. The result is an increase in the size and power of the left ventricle, and it is this strain which may be ultimately responsible for the cardiac failure. The end-result of persistent increase in the diastolic pressure is cardiac defeat. The diastolic pressure is increased by any cause which augments peripheral resistance, either vasoconstriction or actual pathological changes in the arterioles, and it is so intimately related to the elasticity of the arterial walls that it is worth while to refer to this in a little more detail.

Importance of Arterial Elasticity

Elasticity is a characteristic of all arteries, but it is a dominant feature of the aorta and its main branches. During life the elasticity of any artery depends on two factors—its structure, and the pressure exerted on it by the contained blood. In any given artery the latter is a varying factor, and with an increase in the diastolic pressure there is a rapid decrease in arterial elasticity, and an inevitable and corresponding increase in the amount of energy required from the heart.

It is well to remember that in the "make-up" of an artery there are two materials—an elastic, and a relatively non-elastic. With the ejection of blood from the ventricle the elastic element in the aorta first comes into play, and later, when the artery is well stretched, the non-elastic is in evidence. It is clear, then, that a normal artery is much more elastic at low pressures, and becomes more rigid as the pressure rises. It must be equally clear that an artery acts with optimum efficiency at a pressure which allows full play to its elasticity. The relationship between arterial elasticity and blood pressure is therefore of the greatest practical importance. With a rise in diastolic pressure there is a rapid diminution of elasticity, the artery approximates to a rigid pipe, and the work of the left ventricle is increased.

The reason for the extra work required from the ventricle is to be found in the fact that with a low diastolic pressure the elastic artery accepts comfortably the blood discharged from the ventricle, whereas when the diastolic pressure is high the aorta is already stretched and relatively inelastic, and it takes a very powerful systole to produce any further distension. At even extremely high pulse pressures (for example, with blood pressure 200/120, a pulse pressure of 80) the results of each systole are poor.

A high diastolic pressure means a diminished ventricular output per beat. The aorta yields only with difficulty, and even with a much increased heart rate the output per minute falls below the requirements of the body, and anoxaemia is imminent.

At the risk of repeating myself, I would remark that the greater elasticity of the arteries at the lower diastolic pressures is of the utmost value in preserving the heart from undue strain. The aorta acts as a shock absorber, for the arteries are more than tubes. The larger arteries—the aorta and its main branches—are elastic reservoirs, and this elasticity is of importance in saving unnecessary and wasteful effort on the part of the ventricle. The elasticity of the aorta enables rapid distension to take place, followed by slow collapse, and the more elastic the aorta the less the ventricular force required.

An elastic artery saves the heart ; it grasps the blood comfortably. Conversely, any factor which diminishes the elasticity increases the work of the heart, and ultimately the output per minute ; and the most potent adverse factor is a high diastolic pressure, which causes the arteries to become rigid, inelastic pipes. Hence the reserve power of a heart with high diastolic pressure is necessarily very small, and one finds that dyspnoea is usually induced with the slightest effort. Dr. J. C. Bramwell[1] discusses this subject at length, and has shown that the volume elasticity of the arteries is halved between the ages of 10 and 60.

The systolic and diastolic pressures having been recorded, the heart rate and rhythm should be noted at the same time, and also the presence or absence of arteriosclerosis. That gives the complete picture.

Systolic Pressure

In most individuals, as the pressure in the armlet diminishes, each systole is represented by a sound heard from the upper systolic pressure to the diastolic point. Sometimes, however, the sounds, from being sharp and defined in the upper range, fade out as the armlet pressure falls, to reappear as further air escapes. This silent gap may give rise to a faulty reading if the observer only picks up the sounds when they reappear after the gap. In a patient whose systolic pressure is 200 there may be a silent gap from 180 to 160 ; and unless this is recognized a blood pressure of 160 will be recorded as the systolic pressure for that patient. This mistake can be avoided by verifying the systolic pressure as judged by auscultation with that obtained by palpation of the radial pulse.

THE NORMAL READING

There has been a tendency to take as normal a reading definitely too high. It is not uncommon to find the age plus 100 accepted as within normal limits—that is, 160 for a man of 60. This is undoubtedly incorrect. The following[2] is the average of a very large number of records of blood pressure of apparently normal healthy individuals :

Age	Systolic	Diastolic	Age	Systolic	Diastolic
20	120	75	50	130	83
30	123	79	60	135	85
40	126	81			

These figures may be accepted, but it must be remembered that in every individual fluctuations in pressure are constantly taking place under the varying conditions of life, and that even when the record is made with everything in favour of a normal reading it is almost impossible to eliminate all adverse or disturbing factors.

With uniform conditions, a body at rest, and an easy mind, the arterial pressure should approximate to the above standard, and if it diverges markedly repeated estimations should be made. Fluctuations are marked and characteristic in the earlier stages of hyperpiesia. With advancing years the blood pressure becomes less labile and the fluctuations slower ; the fall after a rise is delayed. The compensatory mechanisms are at fault.

Blood Pressure and Exercise

Physical effort is one of the most common causes of a rise in arterial pressure, and this rise is a necessity during exercise, for with muscular effort the blood flow through the muscles in action is greatly increased, and to maintain this increase the output from the heart is doubled or even trebled, and the splanchnic vessels are constricted. As a result the pressure rises, and the active muscles are adequately flushed with oxygen-bearing blood. The increased activity of the heart demands a more liberal supply of blood, and this can only be obtained by a higher pressure in the aorta, for the coronary blood flow is largely dependent on aortic pressure. It is agreed that a " high arterial pressure is essential for the efficient performance of muscular work." It is probable that the higher the work the higher is the pressure.

In the man out of training or engaged in some work with which he is not familiar, the rise in blood pressure tends to be greater than in the man working equally hard at a congenial and accustomed task.[3] As Meakins and Gunson showed, there was an average rise of 31 mm. Hg. in the systolic pressure half a minute after walking briskly up a single flight of thirty steps ; with more strenuous effort a much greater pressure would be reached. Congenial exercise, moderate in degree, in a man under training, after causing a rise in pressure which begins abruptly with the onset of effort, tends to lower the pressure slightly, and proves of benefit. Sir Clifford Allbutt found that " a few weeks of mountain climbing or a cycling tour " was always followed in him by a " lower range of blood pressure, lasting some weeks." I think that there can be no doubt that carefully regulated exercise is one of the most valuable elements in the treatment of patients suffering from high arterial pressure.

Rest, as one would expect, lowers pressure. The work on the heart is diminished, the muscles are relaxed, and the mind tranquil.

Variations During Sleep

Sleep is even more potent, and there is a fall of 20 mm. Hg or more during undisturbed sleep. The greatest fall is noted within the first two hours of sleep, and from this point the pressure gradually rises. During sleep the heart's action and the respiration are slowed, and the general musculature is relaxed, metabolic activity is reduced, with a slight lowering of temperature ; but, as Pr[illegible] pointed out in 1923, this applies only to the peaceful slumber, and in a most interesting section he directs attention to the [illegible] which occur when sleep is disturbed by unpleasant dreams. In disturbed sleep the changes are sometimes very striking. There may be " extreme rise of pressure, increased heart action, with flushing after waking.

The cardio-vascular response to afferent impulses is in the form of a rise in the rate of the heart or a rise in pressure brought about by splanchnic constriction, or both combined. There may be a rise of pulse with little if any rise in pressure, when the heart may be forcible and the cardiac action and vigorous, in response to a great increase in pressure, and the patient may waken to find his heart beating rapidly and forcibly. Professor [illegible]D, records one case in which, during a dream, the pressure rose from 130 to 200. To quote his article :

" The suddenness of development of the functional disturbances in blood pressure, heart action, etc., in the dream state is an important feature. As is well known, most dreams are of very brief duration as regards the actual time occupied, a number of seconds or a very few minutes often sufficing for a dream which is subjectively a long and complicated one—for example, an apparently long and varied dream has been recorded as running its course between the beginning and the ending of a clock striking midnight. The

the many Medical
antly receiving
tics of the
which we

associated functional disturbances may thus be set up with unusual abruptness, as compared with the waking state—as, for instance, in ordinary muscular exertion. It follows that there is little or no time for the coming into play of the various adjustments and compensations in the circulatory and respiratory systems, etc., that are operative in muscular exercise; in the latter the rise of arterial pressure is checked by gradual dilatation of the vessels of the skin and the working muscles, while the heart accommodates itself with the aid of increased coronary blood supply, etc. Thus the blood pressure rise in certain dreams may be both large and steep in ascent. The call on the heart, through its nervous apparatus, etc., may also be a sudden one."

It must have occurred to most of us that it was difficult to understand why cerebral haemorrhage should occur during sleep, when the blood pressure should, if anything, be lower than during the waking hours. And the same difficulty manifests itself in the case of anginal attacks other than those due to coronary thrombosis—seizures which in the daytime may have been induced only by effort or emotional disturbances. Professor MacWilliam has, I believe, supplied the answer. At any rate, sleep can no longer be viewed as a certain haven of peace. The cardio-vascular mechanism is even then liable to be taken suddenly by storm, and, if there be a disease, or a flaw in the arterial tree, disaster may follow.

Effect of Psychological States

On discovering a raised blood pressure we have to form an attitude of its significance, and the first essential is to eliminate the possibility of any transient ephemeral rise due to nervousness on the part of the patient, and then determine how far the cause may be psychical. Such limits as persistent worry, dread, or fear should be frequent for. "Mental pain and physical passivity," the characteristics of melancholia, invariably induce a raised varying pressure, in marked contrast to the relatively low middle age pressure present in neurasthenia and in the active encountered state.

Neurasthenia, characterized by low spirits, depression, and mental fatigue, does sometimes occur in differing from those pathological conditions associated with high pressure. When this High blood pressure a fall in the average pressure of such a symptoms and discovers found that as the indications of neurwise healthy, the pressure rises. The waxing and

Then there is the pressure tends to run parallel with the individual, often nervous of the neurasthenia. When, howa neurasthenic with a ten the neurasthenic symptoms coated tongue. As a contra pressure it is reasonable to infer florid, stoutish, muscular, a true neurasthenic, but rather great driving power, an presenting symptoms simulating tion, and a clean tongue—the

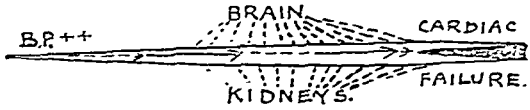
dyscrasism, characterized are we to attach to the presence of increase in weight, an essure? The great difficulty in arriving group there is a steat this is increased when the rise is not which may slowly rising only 30 or 40 mm. Hg above the age—that is, 160 to 170 in a middle-aged an. When the pressure runs to 200 and over, The reading significance cannot be mistaken. Bearing in without fail points we have already discussed, the first step possible, are minate as far as possible any transient rise due actual excitement, emotion, fear, or other similar cause, and further attempt should then be made to determine whether the patient is the victim of persistent worry and anxiety in his home or in his business, and whether he is overloaded with responsibility and cares.

CARDIO-VASCULAR RENAL DISEASE

Having eliminated a psychical cause, we have then to differentiate between a high pressure due to frank renal or cardio-vascular disease, and that of so-called essential hypertension or hyperpiesia, hoping that we may be justified in the latter diagnosis, for the outlook is then more promising, and there is a fair prospect of a satisfactory response to treatment.



The urine should be examined for evidence of nephritis, and tests for the estimation of the renal efficiency carried out. Positive findings are of value, but, unfortunately, the extent of the renal damage must be considerable before there is a measurable increase in the non-protein nitrogen of the blood or a clear depreciation in the concentrating power of the kidneys.

The first object is, then, to classify the patient under one of three heads—namely: (1) hypertension due to psychical influences; (2) hyperpiesia, characterized by high blood pressure with no essential primary renal involvement, but presenting some degree of cardiac hypertrophy and arterial disease; and (3) a renal group—chronic disease of the kidneys in which the high blood pressure is a secondary manifestation.

PROGNOSIS

There is something dramatic and ominous in the steady diminution in the expectation of life accompanying a rise of blood pressure, revealed by a scrutiny of the figures published by insurance companies. This is more marked when the rise in blood pressure is accompanied by obesity; the expectation of life is then still further diminished.

The normal termination in a case of persistent hyperpiesia is cardiac defeat. This is inevitable unless life is cut short by intercurrent disease, some cerebral accident, or by renal complication.

The life-history of the hyperpietic.

Another factor in the prognosis worthy of note is the significance of the age of onset of the hyperpiesia. It is most serious when it appears during the middle period of life, between the ages of 40 and 50.

If the two following tables are compared, the significance of the age of onset becomes apparent, the ratio of actual to expected deaths between the ages of 40 and 49 being 2.21 to 1, while the ratio between the ages of 50 and 65 is only 1.40 to 1. In the first table the 2,634 cases are arranged according to the degree of hyperpiesia; in the second, according to age groups.

TABLE I

Cases	Blood Pressure	Ratio of Actual to Expected Deaths
(a) 1,456	+10 to +16	1.35 to 1
(b) 824	+17 to +23	1.83 to 1
(c) 354	+24 to +30	2.14 to 1

TABLE II

Ages at Entry	Cases	Actual Deaths	Expected Deaths	Ratio of Actual to Expected Deaths
15-39	919	13	11.3	1.15 to 1
40-49	979	53	24.0	2.21 to 1
50-65	736	51	35.3	1.40 to 1
	2,633	117	71.6	1.63 to 1

There is frequently a well-marked familial tendency towards high blood pressure. The knowledge that such a tendency exists in any family justifies the practitioner in recording the pressure, when opportunity arises, in the younger members, so that the first deviation from the normal may be noted, and an attempt made to control the degenerative process. The importance of this is illustrated by the following two cases.

A. H., aged 60. Blood pressure 280/120 mm. Hg; pulse rate 96. Father dropped dead at 46. Both grandmothers found dead in bed at 66 and 64.

Mrs. D., aged 50. Blood pressure 255/130 mm. Hg; pulse rate 90. Father died of stroke at 64. Mother died of stroke at 74. Two sisters died at 45 and 48, both of strokes.

Fluctuations in the pressure are characteristic of the earlier stages of hyperpiesia, and are of favourable significance. Later, when the arteriolar and arterial damage is marked, there is much less tendency to variations. In the advanced cases, if the systolic does fall to any extent below the optimum, it generally indicates myocardial weakness, and is evidence of cardiac failure. The diastolic rarely changes materially, and thus a fall in pulse pressure is an adverse sign, and is generally accompanied by clinical manifestations of cardiac failure and distress, such as an increased liability to dyspnoea, an alternating pulse, a gallop rhythm, or angina of effort. One or more of such signs is ominous.

Auricular Fibrillation

The future is still further jeopardized by the advent of auricular fibrillation, and some of the most dramatic instances of acute cardiac failure are caused by the onset of fibrillation in a patient with marked hyperpiesis. Extreme dyspnoea, accompanied by a sense of constriction in the chest, the skin bedewed with sweat, ashen colour, and a rapid disorderly action of the heart—such are some of the characteristics of the attack. Death may occur in a few hours, or the heart may gradually accommodate itself to the new load, and life may be maintained, though at a much lower level of effort. When fibrillation of the auricle has established itself the expectation of life is very definitely lessened. The acute urgent symptoms described above are those of left ventricle distress; later in the course of the disease congestive failure develops.

The Gravity of Infections

The wider my experience of the life-history of the hyperpietic the more I have been impressed by the importance of infectious illnesses—for example, such transient toxaemias as influenza and tonsillitis.

The first serious depreciation in cardiac reserve and the earliest record of anginal pain are frequently clearly related to a transient toxaemia. The myocardium was hit, and has lost its power of recovery. The practical bearing of this lies in the recognition of the importance and significance of a toxic illness in such patients, and of the necessity for a prolonged convalescence with the administration of haematinics and general tonics.

It is often difficult to convince the active, vigorous hyperpietic that a sharp short attack of influenza is undoubtedly for him a serious matter, and that he must save his myocardium and give it time to recover before resuming his usual activities. Neglect of this advice is often followed by disastrous and irremediable results.

TREATMENT

I am quite aware that, interested as you are in the pathogenesis and prognosis of high blood pressure, you are probably more interested in the management and treatment. Unfortunately, the opportunity for treatment generally arises when the high blood pressure is well established. In any case, the preliminary is a careful and detailed examination and cross-examination—the latter being the more important. It is essential to discover the responsible etiological factors. Heredity, habits of life, diet, the existence of overwork, mental strain, worry, embarrassments (either matrimonial or financial) must be investigated. You must know your man before you tackle his malady.

It is dangerous, not only for the patient's peace of mind, but also for the doctor, to focus attention too persistently on the sphygmomanometer readings. Since a rise in blood pressure is for many patients a compensatory phenomenon, it is obvious that some attempt must be made to determine the optimum pressure in each individual, and not to attempt to reduce it below that level by drugs or drastic remedies. There is some truth in the saying that the greatest danger to a man with a high blood pressure lies in its discovery, because "then some fool is certain to try and reduce it."

General Measures

In the later stages more can be done by careful revision of the mode of life, undertaken with the active co-operation of the patient, than by any drugs prescribed for the specific purpose of lowering the pressure. If the patient is in the early or pre-sclerotic stage, or if the cardio-vascular damage is not advanced, the response to treatment is much more satisfactory, and a great deal can then be done if he will pay the price. When feasible, as a first step in treatment, it is well worth while to order the patient to bed for a few weeks, and at the same time to prescribe a mixture of bromides, or bromide and chloral, with the object of diminishing restlessness and irritability. When the nervous factor is dominant, rest will probably bring about a material fall in the pressure, and those with cardiac symptoms will certainly be benefited. This will afford an opportunity to observe your patient, and to determine in what way and to what degree his manner of life should be modified. Then get him off to the country or to some spa for a month's quiet holiday.

High blood pressure is often the penalty of success—a success the result of continuous hustle and mental strain. The successful man does not walk, he rides. His meals tend to become richer. His friends take advantage of his efficiency; flatter him and impose upon his good nature; and accordingly he is a member of this and that committee, is treasurer of one society and secretary to another, so that the load he has to carry is considerable. While at rest and in the hands of his doctor he must be made to edit the list of his duties and responsibilities, and cut out everything that is not essential to his happiness or his financial stability, so that when he returns to work he has shed that which was irksome and unnecessary. This short period of rest also offers an opportunity for investigating any and every possible source of infection, and it is well to deal with any such focus and to make sure that the teeth are sound and the gums healthy.

In so far as it is possible to remove causes of worry and anxiety, this should be done; occasionally in suitable cases psychotherapy may yield valuable assistance in restoring psychic rest.

To begin with it is wiser not to prescribe drugs, but rather to note the effect of general treatment. Exception may be made, however, in the case of restless and excitable patients; then *bromide, or bromide and chloral*, is valuable; salines and—if necessary—a simple stomachic may be given with advantage.

Regulation of Diet

The diet will require supervision, especially in those who are well above the normal in weight. Every unnecessary pound in weight adds to the load the heart has to carry.

The first essential is to diminish the intake. As one patient put it, after a heart-to-heart talk, "It seems to me that I must keep my head out of the nosebag." I do not believe it wise to give the patient detailed instructions as to diet. He should grasp the main principle—namely, that the diet must be simple, wholesome, and small in amount. "No second helping" is a good rule, and he will do well to remember that "a good cook may be more dangerous to a man in health than a bad doctor when he is sick." He must keep an eye on the scales. If the weight keeps up, the intake of food must go down.

He will probably find it easier to eat less if he takes his meals with a minimum of fluid. Water can be taken on rising, and again before retiring. The starches and the fats should be eaten sparingly, and it is probably wise to refrain from a diet rich in extractives. Gravies, soups, rich stews, and hashes should be avoided, especially when there is evidence of renal damage. Fresh fruits, salads, lettuce, celery, vegetables, milk, and honey should find an honoured place in the menu; and fish, cold boiled bacon, lean ham, and chicken may be allowed. Butcher's meat should be eaten moderately, and beyond the salt used in cooking none should be taken. Alcohol is better deleted from the diet, and any excess in tea, coffee, and tobacco avoided. The diet should be such that the patient likes what he eats, though it is obvious that he should not be allowed to eat just what he likes.

As someone has aptly said, "In few conditions are both the dish of herbs and contentment more essential, or the stalled ox and strife more injurious."

When possible, an occasional day in bed is helpful. In the more advanced cases, with indications of commencing cardiac failure, it is invaluable. During that day the patient should drink plenty of water, lemonade, orangeade, barley water, raisin tea, or weak tea, and refrain from solid food, with the exception of a few biscuits and honey, or an apple.

The Use of Drugs

Drugs, although of secondary importance, have their honoured place in treatment, more especially in the earlier stages. Later they are useful in treating various distressing symptoms—cardiac, cerebral, or renal. The benefit to be obtained in the earlier phases from bromide has already been mentioned, and it is of great service in menopausal hyperpiesia. Mercury, as a blue pill, or a dose of calomel, followed the next morning by a small but concentrated dose of saline, is undoubtedly of benefit. Such a pill should be taken once a week and the saline every morning—not to procure free purging, but one loose rather watery motion each day. Iodine and the iodides are still popular and widely prescribed, either in very small doses, such as 1/10 grain of the iodide, or in the larger dose of 10 grains. Iodine is acceptable either as collosol iodine or as the tincture—five to seven drops of the latter stirred up in an ounce or two of milk is not unpalatable, the small fraction of potassium iodide in the British tincture being an advantage rather than otherwise. If iodism is produced then the French Codex tincture can be used. The myocardium suffers from the toxaemia accompanying any infective illness, especially influenza, and during convalescence (which should be prolonged) haematinics are essential—simple iron preparations with or without arsenic.

There are three drugs which have come more prominently into notice in the last few years: luminal, acetylcholin (acecoline, pacyl), and the sulphocyanates of potassium and sodium. Their tendency is to lower the blood pressure, and their action is evanescent. They are more likely to be of service in the earlier than in the later stage, before gross pathological changes have taken place. Luminal has, in addition, a helpful sedative effect. The sulphocyanates are prescribed in doses of 1½ to 2 grains three times daily after food, the dose being increased gradually day by day. I question whether the nitrites are of any value, except to bring about an immediate and temporary lowering of the pressure.

It is well to remember that the blood pressure is constantly varying both in health and in disease, and that, within certain limits, the normal has been established. When the figures pass beyond this normal there is a corresponding diminution in the expectation of life. It is therefore a physical sign worth investigating in every patient, especially when there is a known familial tendency to cardio-vascular disease. There is here a wide field for study, more particularly for the general practitioner.

MESOTHELIAL REACTIONS IN CHILDHOOD*

BY

JOHN FRASER, M.C., M.D., F.R.C.S.ED.

REGIUS PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF EDINBURGH

I confess I find it a difficult thing to choose an appropriate subject for a lecture such as this. It is a privileged opportunity to address a gathering of men who are engaged in general practice, and I would like to justify that opportunity by presenting to you a subject which will be both interesting and helpful. It is in that very ambition that my difficulty lies, for I would like to leave the beaten tracks of stereotyped subjects and venture into fields that are as yet but little understood and largely unexplored. I know that when we leave the broad highway our footsteps often tread on sinking sands, and the foundation that we fondly thought was firm and sure may crumble into fragments when we rest upon it. None the less there is an interest—an adventure—call it what you will—in venturing into new territory, and in a very small and modest way the subject I propose to present to you may be said to justify the description, so alluring to the mind of the average man, of "terra incognita." If by these introductory remarks I seem to weave a veil of mystery where no secret really lies, it is because I appreciate that what I have to say is based, in part at least, upon hypothesis, supported, it is true, by a certain measure of experimental evidence and a framework of clinical observation. The purpose of my paper is to present to you certain reactions of the mesothelial spaces of the body, and more especially of the great mesothelial space—the peritoneal cavity.

A CASE HISTORY

Some months ago a boy of 6 years was admitted to the Edinburgh Royal Infirmary. The summary of the case history was as follows: Ten days before admission he complained of a sore throat, there was a rise of temperature with general illness, and a diagnosis of acute tonsillitis was made. Four days later, under appropriate treatment, the local infection subsided, and the boy appeared to be convalescent,

* A British Medical Association Lecture delivered to the Ayrshire Branch, March 19th.

but at the end of a further forty-eight hours there was a recurrence of illness, the temperature rose again, there was abdominal pain and vomiting, and considerable constitutional disturbance. The usual simple remedies failed to produce improvement, and further examination showed that an acute peritoneal infection had developed. When the child was admitted to hospital, ten days after the original onset of symptoms, he was found to be suffering from a generalized peritonitis, and it was our view that the infection had arisen secondary to an inflamed appendix.

Operation revealed an interesting state of affairs. The peritoneal cavity contained a considerable amount of purulent fluid, but we were unable to discover any localized infection from which the peritonitis could have arisen. The appendix was normal, and a careful exploration of other regions yielded negative results. The condition might be described as an idiopathic generalized peritonitis—an unsatisfactory diagnosis, and we preferred to regard the peritoneal infection as secondary to a generalized blood infection originating from the tonsillitis. The organism recovered from the peritoneal fluid was a streptococcus, and, though no blood culture investigation was done preceding the operation, the clinical history suggested that a septicaemia existed. It was therefore our view that the tonsillitis had induced the septicaemia, and that the peritonitis arose as a secondary blood-borne infection. Such was the position, but it is my purpose to elaborate the problem and to present other possibilities for your consideration.

THE STRUCTURE OF THE PERITONEUM

When we examine the structure of the peritoneum we find that it is arranged on an essentially simple plan; a layer of flattened cells rests upon a connective tissue basis which carries the lymphatic and blood vessels (tunica propria). On surface outline the cells appear to be pavement epithelium, but on profile they are seen to be imperfect pyramids with truncated apices and sloping slides. Such being their outline, there are ditches or fossae between the individual cells, and contiguous cells are in contact only at the fringes of their respective edges. There has been much surmise on the *raison d'être* of this peculiarity in structure, and it has been suggested that the relative insecurity of contact between individual cells permits the passage of leucocytes and connective tissue phagocytes from the deeper tissues to the surface, and vice versa. It will be recalled that when the peritoneum is stained by the silver nitrate method a network-like arrangement interspaced with punctate points is evident. It was thought at one time that this appearance was produced by stomata, apertures which established continuity between the peritoneal surface and the underlying lymphatics; in all likelihood deposits of silver stain in the ditches explain the appearance, and it is doubtful if actual stomata exist. I would add that the peritoneal cells, while capable of great reparative power, so that wounds of the surface are rapidly healed, have relatively small phagocytic activity, this function being mainly assumed by phagocytic leucocytes and connective tissue corpuscles.

THE ORIGIN OF THE PERITONEUM

What is the source from which peritoneal tissue has arisen? The peritoneum originates as a split in the mesoblast, and the method of its production is similar to that which occurs in the formation of certain joint spaces and in the pleura. It is therefore obvious that the cells which line the peritoneum are specially adapted mesoblastic cells, and, because they adopt the function of space-lining, they are appropriately termed "mesothelium." The terms "epithelium" and "endothelium" are often applied to the structure, but, as Professor Mall has shown, they are misnomers.

THE FUNCTION OF MESOTHELIAL SPACES

We may now inquire why this special adaptation of the mesoblastic area arises. Why should a mesoblastic split occur, and what is the reason for this peculiar structural metaplasia of the cells? In other words, what are the functions of mesothelial spaces, and of the peritoneal space in particular?

We may learn something if we consider the question from the morphological standpoint. In the most primitive types of organism the digestive tube courses through a mesoblastic field. It is in the Annelidae that we find the first suggestion of a peritoneal space. It has arisen as a split in the mesoblastic tissues which surround the digestive tube, and it is significant that it contains large numbers of leucocytes suspended in fluid, the function of which is to destroy parasites which have passed through the gut wall. From evidence such as this it is reasonable to argue that one of the reasons for the formation of the peritoneal space is to develop a protective barrier between the dangerous area of the digestive tube and the tissues which lie in relation to it. The earliest and original function is the basic and primitive one of body protection. I agree that it is difficult to ascribe such a function to the mesoblastic spaces of joints, and even of the pleura, but, where the peritoneum is concerned, the argument is appropriate, and, as we shall see, evidences are apparent of the same inherent quality when we consider the reaction of other mesothelial spaces to disease.

The second function of the peritoneal space is to permit freedom of mobility and motility of the viscera which lie within its confines. At first sight this would seem to be the most important and obvious function. It is one which has become elaborated as the complexity of the digestive tube has increased, but it is probably correct to regard it as acquired and secondary rather than primitive and original. Clinical experience tells us that the space capacity of the peritoneal area may be obliterated by a widespread adhesive process while comparative efficiency of the related viscera is retained, a demonstration of the fact that the "space mobility" function is not as essential as might appear. The peritoneal space and tissue exercise a third function, which is physiological. They are concerned in the secretion and absorption of fluid, changes which imply the physical processes of osmosis and dialysis. We know comparatively little regarding the stimuli which induce these changes or the ways in which the reactions are beneficial, but the processes are being constantly exercised, both in health and in disease.

Such are some, probably the most important, of the functions of the peritoneum and of its associated space; it will be noted that they may be grouped as protective, mechanical, and physiological.

THE NATURE OF THE PROTECTIVE FUNCTION

Let us now focus our interest on the protective function. Mesoblastic tissue would appear to be essentially supporting in purpose and design; it forms the bulk of the body tissues, the bone, and the muscles, but where it splits and where certain of its cells become adapted as a lining substance or mesothelium, such portions of the mesoblast appear to exhibit changes in the existence of infection which I believe we shall some day regard as protective in character. Let me recall experimental evidence which has a bearing on this matter. In 1929 Herrmann published in the *Bulletin of the Mayo Clinic* the results of an experimental inquiry on peritonitis. He encountered the difficulty which previous investigators had experienced in inducing an experimental peritonitis similar to the state which we meet with clinically. The intraperitoneal injection of a small quantity of infected material produced no apparent result, owing to the exercise of the phagocytic and antibacterial influences of the peritoneal area, while the injection of a larger quantity resulted in death from septicaemia before local evidences of peritonitis were appreciable. Herrmann attempted to overcome the difficulty by increasing the immunity of the subject prior to

the inoculation For this purpose he employed a combination of the *Bacillus coli communis* and the *Streptococcus viridans*, and a vaccine prepared from this symbiosis was injected on successive occasions over a period of some weeks Animals so prepared, when injected intraperitoneally with an amount of infection which under ordinary circumstances would have proved fatal from septicaemia, developed a purulent peritonitis virtually similar to that which we encounter clinically These experiments, while not fully conclusive, indicate that a peritonitis develops in coexistence with a certain degree of immunity, that in the absence of immunity no local reaction develops, and death ensues from general infection, while in the existence of a fully developed immunity there is no local reaction, because the infection is overcome as soon as it is introduced

THE MEANING OF IDIOPATHIC PERITONITIS

It is now appropriate to recall the circumstances of the case I outlined at the beginning of this address If we correlate the case history with the various points I have discussed, we may build up an interesting, though hypothetical, explanation

Our little patient developed a septicaemia secondary to the acute tonsillitis which introduced his illness He might have succumbed to such an infection, but fortunately he possessed sufficient resistance to develop a specialized field of immunity That field was located in the largest and most active mesothelial region of the body —the peritoneum He developed, in fact, what the older clinicians termed a " fixation abscess," a state which they used to induce by the subcutaneous and intramuscular injection of turpentine, and that which was regarded in the case under discussion as a most regrettable development, a purulent peritonitis, was really an attempt on the part of the body to induce a local field of reaction from which a general immunity would result I appreciate that the infection was conveyed to the peritoneal area by the blood stream, but so it was to every other portion of the body, the significance lies in the specialized reaction which the mesothelial tissues demonstrate

If we regard the problem in this way our conception of various infective conditions is modified There is a polyarthritis associated with a streptococcal septicaemia, sometimes spoken of as Still's disease In it we are probably witnessing a very similar process to that which we have been discussing—the joint changes are mesoblastic and mesothelial responses to a general blood infection, and in the adult the proliferative type of rheumatoid arthritis may well have a similar explanation I believe that, as our knowledge develops we shall increasingly appreciate the significance of the mesothelial response to general infection, but for the moment our interest is centred on the peritoneal mesothelium From what we have seen, the response of this tissue is chiefly evidenced in childhood, and more particularly in the early years of that period The protective association is then at its maximum, and as age proceeds, the response tends to diminish, perhaps to disappear

THE MESOTHELIAL REACTION IN PNEUMOCOCCAL PERITONITIS

Some years ago I was interested in the question of pneumococcal peritonitis, and the investigation which was carried out at that time in conjunction with Dr MacCartney seemed to indicate that in female children the peritoneal infection probably arose in consequence of a spread through the genital tract into the pelvic peritoneum In view of what I have since observed, I am inclined to believe that the majority of pneumococcal peritoneal infections are examples of a mesothelial reaction to a pneumococcal septicaemia, and that the cases which survive are those which show the degree of peritoneal reaction which results in a purulent peritonitis

Too often there is an insufficient immunizing response, and all that we discover is the deep blush of a congested peritoneum with but a scanty effusion of turbid fluid, findings which indicate the insufficiency of resistance and the hopelessness of the ultimate prognosis

PERITONITIS IN RELATION TO NEPHRITIS

Let me recall one further point in relation to the part which the peritoneum plays in the general infections of childhood

Last summer a boy of 5 years came under my care with the following history Some weeks previously he developed acute nephritis, the urine contained a large amount of albumin and there was considerable body oedema, with marked ascites The general condition improved under medical treatment, but the albuminuria and ascites persisted On the evening of July 12th acute abdominal pain was complained of, the temperature rose from 99° to 102°, and general abdominal tenderness was elicited on palpation I saw the boy for the first time the following morning The clinical features were those of an early generalized peritonitis Dr Charles McNeil recalled that Holt had described the development of a streptococcal or a pneumococcal peritonitis in association with nephritis and ascites and in this case Dr McNeil had made the diagnosis of a pneumococcal or a streptococcal peritonitis A laparotomy was performed, and we found the abdominal cavity filled with turbid fluid, there was no localized infection, and from the fluid a pneumococcus was isolated and cultured The findings were those of a generalized pneumococcal peritonitis The real interest, however, lies in the sequel Within five days the albumin vanished from the urine, the tissue fluid disappeared and an uninterrupted recovery was made, the child to-day enjoys apparently perfect health It is not unreasonable to recognize in this case an example of an immunizing response of the mesothelial tissues The kidney error was local evidence of a general infection, the peritonitis was an attempt at an immunizing experiment and though we interrupted the development of Nature's intention sufficient had been achieved to eliminate both the local and the general errors

THE PROBLEM OF TREATMENT

If we accept the view that an immunizing peritonitis arises in childhood in association with certain types of general bacterial infection, the proper course to adopt in relation to it gives us anxiety If we intervene too early we are interrupting a process which is protective, and therefore salutary, on the other hand, because the reaction arises in a closed space and in an area from which absorption will ultimately occur, a time comes when intervention in the form of drainage is essential if disaster is to be avoided I suppose the truth is that, as we are unlikely to recognize an immunizing peritonitis until it is demonstrated by laparotomy, we shall continue to intervene, the time is not yet when we can say, " *Cunctando restituit rem* " I would add that, while there is no doubt a time of election at which operative intervention is most appropriate, less harm arises from early operation than from undue delay

And now the demon of doubt has entered my mind Have I erred in drawing attention to this question? Shall I be accused of the heresy of advising conservatism in peritonitis? I hope no such construction can be placed on what I have said, but perhaps I should insist that the condition I am discussing is the generalized peritonitis developing in the absence of any local inflammatory or perforating lesion a peritonitis which is the result of the response of a certain type of tissue to a general infection, a response which I believe, we may regard as protective and immunizing in its character, a phenomenon (and this is important) which is exercised in its maximum degree in the years of childhood.

A Clinical Lecture
ON
HOUR-GLASS CONTRACTION OF THE STOMACH

DELIVERED AT GUY'S HOSPITAL, APRIL 16TH, 1931,

BY

R. P. ROWLANDS, M.S., F.R.C.S.
SURGEON TO GUY'S HOSPITAL

I venture to illustrate this lecture with accounts of my first and of my latest case of hour-glass contraction treated by operation. I published a detailed description of the first and most remarkable case, with five others, in the *British Medical Journal* of March 25th, 1911, and in *The Operations of Surgery* (1927, ii, 188). The latest patient has only just left Guy's Hospital.

CASE I.—*Hour-glass Contraction : Duodenal Stenosis : Gastro-gastrostomy and Finney's Operation*

Mrs. M. D., aged 42, came to me in 1909 with a history of indigestion for many years, and of almost constant pain in the epigastrium and sternum for the last three years. Swallowing immediately made the pain worse, and was followed by vomiting, which eased the pain. Only two or three ounces of liquid could be taken at a time ; solids always caused severe pain and vomiting. There was no history of haematemesis or of melaena. The patient was very thin, sallow, and weak, and said that her weight had gone down from 130 lb. to 56 lb. during the last two years. A physician had seen her, and had diagnosed incurable malignant disease of the stomach or oesophagus. Radiographic examination after an opaque meal excluded oesophageal obstruction, but showed tight hour-glass contraction of the stomach, with a very small upper pouch and a very large lower one, with definite pyloric stenosis. Gastro-gastrostomy was performed with great difficulty owing to the small size and high position of the upper pouch ; the incision in the latter had to be made almost circumferential in front of the greater curvature in order to get a sufficiently large anastomosis. The pylorus was then enlarged by Finney's operation. There were many gall-stones in the gall-bladder, but the temptation to remove them was resisted. The patient made a good recovery, and had gained over a stone in weight before she left the nursing home five weeks later. In 1912 she weighed over 9 st., having more than doubled her weight. In 1913 I removed a number of gall-stones from the gall-bladder and cystic and common bile ducts. The patient has remained perfectly well ever since.

CASE II.—*Hour-glass Contraction : Partial Gastrectomy*

E. H., aged 44, was admitted, under Dr. A. F. Hurst, on February 18th, 1931, for severe and continuous pain in the left side of the abdomen and the back, which occurred at intervals of two or three months for the past four years. Her brother had a partial gastrectomy for gastric ulcer. She had five children, having had also severe pelvic peritonitis after the birth of her first child, twenty-one years ago. Six years ago she had a hysterectomy, with removal of both ovaries ; afterwards she was ill with double pneumonia and in bed for seven months. Four years ago she began to suffer from severe pain in the left hypochondrium, with nausea, vomiting, constipation, and retention of urine. These attacks would last for two or three weeks, and then would give way to a period of comparative freedom from symptoms, lasting for about three months, but even then there was a dragging pain under the left costal margin. The attacks gradually became more frequent until, finally, just before Christmas, 1930, she had an attack which was much more severe than any previous one, and lasted until she was admitted on the above-mentioned date. She usually vomited about two or three times a week. On admission the patient was weak and anaemic. The teeth were in bad condition, and showed extensive caries. The abdomen was full, and showed numerous brown stains, due to the application of heat. There was resistance and tenderness in the left hypochondrium, and the pain was referred to the left breast and left shoulder-blade. The urine contained albumin, with a little pus, and gave a culture of the *Bacillus coli communis*. An *x*-ray examination of the renal tract showed no abnormality ; the Wassermann test was negative. The pain was almost continuous, but was worse very soon after food ; nausea and vomiting followed the pain. *X*-ray examination after a barium enema demonstrated no abnormality. After an opaque meal had been given, an hour-glass stomach was visible, with a large niche about the middle of the lesser curvature. This was tender on pressure, and was thought to indicate an ulcer penetrating the pancreas. The notch on the greater curvature opposite the ulcer was very deep, but although the channel for food was very narrow, the barium passed quite freely from the upper into the lower pouch. The duodenal cap was normal, but about half the meal remained in the lower pouch of the stomach at the end of six hours. Although the patient improved a good deal on a strict diet, Dr. Hurst did not think the deep and large ulcer would heal under medical treatment, nor did he expect gastro-gastrostomy would be sufficient, especially as there was no delay in the upper pouch. The patient was therefore transferred to my ward on March 19th. As the haemoglobin was 80 per cent., transfusion was considered unnecessary.

At operation, on March 26th, using the left Kocher incision, many adhesions were found in the lower abdomen from the old hysterectomy. There were some calcified glands in the mesentery, especially near the ileo-caecal angle. The appendix did not appear to be diseased, and was not removed. There were many calcified glands in the ileo-caecal region. There was no duodenal ulcer or stenosis. A large ulcer was found at the middle of the lesser curvature, whose crater just admitted the tip of my thumb. There was only a moderate hour-glass contraction ; most of the deformity shown on the *x*-ray pictures was clearly due to spasm, and as the ulcer was deep and partly adherent to the pancreas, and appeared to penetrate the stomach wall, Dr. Hurst (who was present) and I decided in favour of partial gastrectomy. This was carried out, the stomach being divided 1 inch from the pylorus and the adhesions to the pancreas being tied and the stomach divided 1½ inches above the ulcer and joined to the jejunum 8 inches below the duodeno-jejunal flexure, the proximal part being at the greater curvature. When the operation had been completed the distal jejunum appeared kinked and compressed by the root of the transverse mesocolon ; therefore an entero-anastomosis was made. During the operation a grey swelling, 1 inch long, was found in the early part of the jejunum, which was suggestive of tuberculous ulceration. The anastomosis was made below this part. No other similar patches were found. After the stomach had been removed the mucous membrane about the ulcer was seen to be very oedematous and congested, and this made the ulcer seem deeper than it really was. It had not quite pierced the outer coat of the stomach.

ETIOLOGY

Hour-glass contraction is nearly always due to a peculiarly chronic kind of gastric ulcer, which is very rare in men but fairly common in women. It generally occurs near the middle of the lesser curvature, but occasionally it may be found much higher or lower down. Opposite the niche of the ulcer on the lesser curvature a deep spasmodic notch is formed on the greater curvature. Gradually the ulcer extends deeply into the gastric wall and causes extensive infiltration of it, especially where it is in spasm. It has a great tendency to heal with the formation of dense scar tissue, which draws up the greater towards the lesser curvature, causing more and more obstruction, with secondary dilatation and hypertrophy of the upper pouch. Spasm of the muscular coat of the stomach and congestion with oedema of the mucous membrane add to the obstruction. These factors vary

from time to time, so that the degree of obstruction is also variable. It is interesting and significant that the type of ulcer which causes hour-glass contraction very rarely becomes malignant. This well-recognized fact has great influence in making the surgical treatment easier and safer and the ultimate prognosis better.

At one time it was thought that this deformity was congenital in origin, a reversion to the type of divided stomach seen in some of the lower animals. There is only one authentic case of congenital hour-glass contraction. In one case the deformity was secondary to a congenital gastric fistula. Bands outside the stomach may squeeze it into an hour-glass shape. I have seen several cases of this kind. In one of these the contraction had followed the perforation of a gastric ulcer with diffuse peritonitis. After some months, a broad band of adhesions remained and passed round the stomach from the ulcer, which was on the lesser curvature and adherent to the liver. In another, a thin band constricting the upper part of the stomach extended from calcified glands above the pancreas. Occasionally syphilis causes hour-glass contraction, and therefore it is always wise to make the Wassermann test. *Carcinoma causes about 1 per cent.* of hour-glass contractions. The *x*-ray appearances differ much from those of simple hour-glass contraction.

VARIETIES

Usually the ulcer causing the stricture is near the middle of the lesser curvature, and the upper pouch is larger than the lower, but occasionally the ulcer may be very high up, near the cardia, so that the upper pouch may be very small. Sometimes the ulcer may extend to the cardiac orifice and cause not only an hour-glass contraction but also oesophageal obstruction. Rarely an ulcer near the pylorus may cause an hour-glass contraction with a *small lower pouch*. In about one-third of the cases, duodenal or pyloric stenosis complicates hour-glass contraction; this has been overlooked before and during operation with serious consequences.

Instances are recorded of two or more contracting ulcers of the stomach dividing the latter into three or more pouches. The contracted part of the stomach is nearly always adherent to the under surface of the liver, the pancreas, the falciform ligament, or the anterior abdominal wall. In the majority of my cases the ulcer had healed or was quite small before the patient came to operation, so that there was no suspicion of malignancy or need to excise an ulcer or stricture, but only to make a good short circuit for the free passage of food.

DIAGNOSIS

Before the introduction and perfection of radiographic examinations the diagnosis of hour-glass contraction was often difficult, and we had to rely upon gaseous distension of the pouches. Nowadays, careful and repeated *x*-ray examinations make the diagnosis easy and accurate. It is possible, however, to overlook the lower pouch if the stricture above it is very tight, and if repeated examinations are not made after the food has had time to pass into the lower pouch. The notch produced by muscular spasm opposite an ulcer upon the lesser curvature has often led to erroneous diagnoses of hour-glass contraction, so that when the stomach has been exposed at operation the spasm has been overcome by the anaesthetic, and very little narrowing of the stomach has been evident. But, as already mentioned, spasm and oedema of the stomach add greatly to the obstruction produced by real fibrous contraction. The waist of an atonic stomach dragged down by an opaque meal is quite different from that of true organic hour-glass contraction. It does not show the bulge or pouch below and to the left of the stricture. Reflex spasmodic contraction of the stomach has led to a wrong diagnosis. In one case of this kind, hour-glass contraction was demonstrated on three separate occasions, but none was found at the operation. A subacutely inflamed appendix lying in the pelvis and full of pus had caused the reflex contraction, and its excision cured all the reflex gastric symptoms and signs.

TREATMENT

Although medical treatment may greatly relieve the symptoms of hour-glass stomach in its early stages, an operation should be performed as soon as obstruction develops, for it is rarely possible to cause the ulcer to heal completely without seriously increasing the obstruction. Delay has often led to unnecessary suffering and semi-starvation. Many of my patients had become extremely thin and weak before they were sent for operation. Delay may also lead to serious haemorrhage, perforation, or possibly malignant disease. A subphrenic abscess had developed in one of my patients, and had existed for nearly three months before the operation; it is no wonder, therefore, that she died a few days after the operation.

PREPARATION FOR OPERATION

The patient should be carefully prepared for the operation, and all septic conditions, especially in the mouth, throat, and nose, should be efficiently treated at least a fortnight beforehand. The stomach is washed out if there is much stasis, and, after this, the diet should be limited to sterile liquids for two days before the operation. Rectal salines with 5 per cent. glucose may also be given with advantage in severe cases.

The operation should begin as a rapid exploration of the whole abdomen, and any obvious source of infection, such as a diseased appendix, should be treated. The stomach, pylorus, and duodenum must be carefully examined, for without this precaution a cardiac pouch, a trilocular stomach, or associated duodenal obstruction has been overlooked, with disastrous consequences. In six cases mentioned by Veyrasset[1] the upper pouch was overlooked, and only the pyloric pouch was drained by a gastro-jejunostomy, with fatal results. The exact nature of the operation must depend on the conditions found on exploration, for the same operation is not suitable for all cases. Much depends on the size of the cardiac pouch, the presence or absence of pyloric obstruction or adhesions, and any suspicion of malignant disease. The condition of the patient has also to be taken into consideration, for this is frequently too bad for a long and severe operation.

The immediate need is to overcome the obstruction, so that the patient may be saved from starvation. Under these conditions excision, which may seem to some to be the ideal radical operation, may be far too dangerous, and therefore wrong. Experience has also shown that it is rarely necessary.

Hour-glass contraction depends chiefly on the formation of scar tissue in connexion with a chronic ulcer. Recovery under medical treatment is prevented by the increasing obstruction, with the consequent starvation and the forcing of food through the narrow neck of the hour-glass over the surface of the ulcer. When the obstruction is overcome by operation, the food is no longer driven over the ulcer, *full diet can be taken with safety, and complete* healing may be expected; there is abundant evidence that this does take place.

CHOICE OF OPERATION

The choice of operation depends chiefly on the presence or absence of pyloric obstruction in addition to hour-glass contraction. It follows that the discussion will be facilitated by adopting this natural division.

Simple Hour-glass Contraction

Gastro-gastrostomy is, in my experience, the most commonly applicable and satisfactory operation; when well done it permanently overcomes the obstruction without altering the physiological conditions of the stomach, and without trespassing on the ulcerated stricture, through which the food need never pass again. Moreover, it is the safest operation, and it carries no risk of gastro-jejunal ulcer or of vicious vomiting, which are especially likely to follow gastro-jejunostomy performed under unusual difficulties. When the upper pouch is very small, gastro-gastrostomy may be difficult, but by making a curved incision a sufficiently large opening can be obtained. The vertical gastric incisions figured in some of the books cannot be made nearly long enough to provide adequate drainage. This operation is much more easily done on the front of the stomach for adhesions in the lesser sac, and the distortion of the stomach makes a posterior operation very difficult without any compensating advantages. The essential points of gastro-gastrostomy now require attention. It is of vital importance to make the stoma as large as possible, especially when this is the only operation performed. With this object very large pouches of the cardiac and pyloric parts of the stomach are so secured in strong curved clamps that long curved incisions can be made in them about 1 inch above and nearly parallel to the greater curvature. The points of the clamps are just below and in front of the structure, and their handles below the greater curvature well to the right and left. The pouches are brought together and joined by two continuous fine catgut sutures as in gastro-jejunostomy.

Gastroplasty, as advocated by Kammerer, is not nearly so satisfactory because it trespasses upon the stricture or ulcer; consequently haemorrhage is more likely to follow, and the sewing is more difficult owing to the adhesions which generally bind down the contracted part of the stomach.

Gastro-jejunostomy.—When there is no pyloric obstruction and the cardiac pouch is of large size, posterior gastro-jejunostomy, engaging the lower part of the cardiac pouch, is attractive, because it not only overcomes the gastric stricture in a simple way, but it also corrects the excessive secretion of acid, which is such an important cause of the persistence of the ulceration when a low gastric stricture has once formed.

Excision of the Ulcer.—In some cases it is possible and advisable to excise the ulcer upon the lesser curvature without approaching too near the greater curvature. When the V-shaped opening thus made is closed, the narrowing is abolished, and the natural shape of the stomach is restored. This operation has the merit of immediately removing a chronic ulcer, which is slow to heal and may be regarded as a possible source of malignant disease, but it is unnecessarily difficult and severe for bad cases, and is only to be undertaken at any time by surgeons of considerable skill and experience in gastric surgery. Recurrence of ulceration with more severe hour-glass contraction occurred within a year in one of my cases; gastro-gastrostomy was then performed, and proved satisfactory. It must always be remembered that gastro-gastrostomy, which is a comparatively easy operation, cures these patients at a much smaller risk.

Partial Gastrectomy.—Removal of the part of the stomach bearing the stricture either by sleeve resection or by the classical partial gastrectomy is recommended by some surgeons, but as a rule it is unnecessarily severe and exposes a feeble patient to unnecessary risk. It is certainly necessary in a few cases, especially when the ulcer is large or when malignant disease is present, or even then there is reason to suspect it. I have operated on over sixty cases of simple hour-glass contraction, and only one patient who had had an attack which was much worse than any previous one, and lasted until she came under my care for the above-mentioned date. She usually had hour-glass contractions at two or three times a week. On admission she was very emaciated, was weak and anaemic. The teeth were in bad condition, and showed extensive caries. The abdomen was scaphoid and the proximal loop of jejunum could be seen and felt as a tense cord. The patient had completely recovered, and she has remained quite well and able to work hard for six years following the operation.

Retrograde Dilatation.—Moynihan[2] records a remarkable case in which it was impossible to join the cardiac pouch to the pyloric pouch or jejunum owing to adhesions. He opened the pyloric pouch and dilated the stricture in a retrograde manner, and to his surprise the patient made a good recovery.

Temporary jejunostomy has been performed in some cases when no other operation could be done with advantage (Eusterman).[3] The rest afforded to the stomach for some months may improve the local conditions so much that a secondary radical gastric operation may become possible.

Hour-glass Contraction with Pyloric or Duodenal Stenosis

Gastro-gastrostomy followed by Finney's Operation.—I prefer this combination whenever possible. When the pylorus and duodenum are movable Finney's operation appears to be the best method of overcoming duodenal stenosis, for it is simple and effective, and can be performed very quickly when time is important in these enfeebled patients requiring two anastomoses, and particularly because it carries no risk of vicious circle or gastro-jejunal ulcer. Sometimes lateral gastro-duodenostomy is easier and better, but gastro-jejunostomy is preferable when there is active ulceration with deep and firm fixation of the duodenum.

Double posterior gastro-jejunostomy is not satisfactory in these circumstances for various reasons. It is difficult to drain the two pouches thoroughly through the limited space available in the mesocolon. Moreover, there are as a rule extensive and firm adhesions behind the stomach, and the mesocolon may be considerably shortened and adherent. In some of my cases it seemed impossible to join the jejunum to the posterior surface of the very small cardiac pouch, without undue risk of angulation and obstruction of the long-drawn-up loop of the jejunum around which the mesocolon, although sewn to the stomach, is very likely to contract.

Partial gastrectomy is worth considering when duodenal ulceration or duodenal stenosis complicates hour-glass contraction in a patient who is not too feeble, but so far I have been content with the simpler and safer methods described above.

RESULTS OF OPERATION

Mortality.—Veyrasset's[1] statistics published in 1908 show a mortality of 16 per cent. for 260 operations for simple hour-glass stomach, but six of the deaths were due to draining the pyloric instead of the cardiac pouch. The death rate has much diminished since then, especially when great care is taken to select the operation, or combination of operations, most suitable for each case. As a rule gastro-gastrostomy is applicable and is attended by a very small risk, considering the state of nutrition of these starved patients. I have operated on over sixty cases with only two deaths due to the operation. It is fair to put the mortality at under 4 per cent.

Ultimate Results.—These are very good when the obstruction is thoroughly overcome. In the majority of my cases I have adopted gastro-gastrostomy and added either Finney's operation or gastro-jejunostomy when it was necessary to overcome duodenal stenosis. Very few of my patients required a secondary operation. There were three secondary gastro-jejunostomies, one secondary partial gastrectomy, and one secondary gastro-gastrostomy seven years after the first.

VITAMIN B_2 AND PELLAGRA

THE ETIOLOGY OF PELLAGRA

BY

B. C. GUHA, PH.D., M.Sc.

TRAVELLING FELLOW OF THE UNIVERSITY OF CALCUTTA

(From the Biochemical Laboratory, Cambridge)

The purpose of this article is to direct attention to the fact that, though Goldberger's researches have thrown very considerable light on the question of the etiology of pellagra, there are several points in this problem which are still obscure. The earlier theory that pellagra was caused by a deficiency of protein of good biological value was discarded by Goldberger after a series of researches, in which he found that, while caseinogen provided little relief, certain materials like brewer's yeast and fresh meat afforded both protection and cure.[1 2] Convincing evidence was advanced by Goldberger and Lillie,[3] who produced a pathological condition in rats by giving them an alcoholic extract of corn-meal, which is known to be rich in the so-called antineuritic factor, as the sole source of water-soluble B. This condition was characterized by a failure of growth, loss of fur, and buccal lesions, and was considered to be the experimental analogue of human pellagra. Inclusion of yeast, in which the antineuritic substance was almost completely destroyed by autoclaving, cured and prevented all these symptoms. These experiments, confirmed by others,[4] have led to the general belief that the water-soluble B of McCollum consists of a relatively heat-labile factor which is specific for polyneuritis and a more thermostable constituent (Goldberger's P-P factor) which is concerned in the prevention and cure of pellagra. These two factors have now been respectively designated as vitamins B_1 and B_2 in this country.

ETIOLOGICAL CONSIDERATIONS

In spite of the above work, however, it is not yet clear whether pellagra, experimental or human, is the result of an uncomplicated deficiency of the factor called vitamin B_2—that is, the substance which supplements a purified preparation of vitamin B_1 for the development of vitamin B deficient rats. Nor is it certain that the dermatitis condition in rats is a perfect analogue of human pellagra. This condition in rats cannot be produced uniformly by the deficiency of vitamin B_2 in the diet. Attention is drawn to statements in the literature[5 6] that pellagra symptoms in rats may be produced when they are still growing, while, very often, the arrest of growth in vitamin B_2 deficiency is not associated with any skin symptoms. Elsewhere[7] I have described a curious kind of depilation in rats subsisting on a vitamin B_2 deficient diet, in which the fur fell off not in patches, but uniformly. This occurred fairly regularly when young animals were kept on a vitamin B_2 deficient diet with only occasional administrations of small doses of vitamin B_2, such that the deprivation of vitamin B_2 was not complete, but sufficiently severe to cause the weight of the animals to remain between 60 and 80 grams over a period of ten to twelve weeks. Lesions on the mouth and paws occurred only in a minor proportion of these animals. The symptom of depilation was rapidly cured by administration of Eli Lilly's liver extract No. 343. Leader[8] has recorded that small doses of marmite, sufficient to prevent beri-beri, are actually helpful in the production of pellagra-like symptoms in rats, an observation which is supported by the work of Sure and Smith.[9] It has been pointed out by Aykroyd[4] that rice, millet, and maize are all poor sources of vitamin B_2 as tested on rats, while human pellagra appears to be associated chiefly with the consumption of maize.

Bliss[9] has recently put forward the view that human pellagra, as well as experimental pellagra in rats and black tongue in dogs, is caused by iron deficiency. In a more recent paper[10] he has adduced fresh evidence in support of his claims. He observed depilation occurring in rats on an iron-deficient diet containing ample vitamin B; according to Elvehjem and Peterson,[11] hair is the richest source of iron in the body. The depilation of our rats on a vitamin B_2 deficient diet cannot, however, be due to a simple iron deficiency, as the food intake and, therefore, the iron intake was still sufficiently large to cover the iron requirements of the animal. This condition of depilation was not remedied, nor did growth resume on feeding 25 mg. of haemin per day. The haemin was dissolved in 0.2 *N* NaOH and precipitated in a finely divided condition by 0.2 *N* HCl, this suspension being fed in various doses. The dose fed was much in excess of that which could be absorbed by the animals, as was shown by a considerable excretion of haematin, indicated by the benzidine test. Nor did the condition improve on feeding 0.5 gram of haemoglobin per day. However, the experiments with haemin may have been complicated by an insufficient absorption from the gut, and hence they cannot be strictly compared with those of Kollath,[15] who states that the feeding of alkaline haematin prevents the appearance of pellagra symptoms in rats on a diet deficient in vitamin B. The fact that vitamin B_2 in certain preparations can be inactivated by autoclaving in an alkaline medium[12] argues against the proposition that vitamin B_2 deficiency is simply an iron deficiency. The possibility, however, must be recognized that pellagra, both clinical and experimental, might be associated with a disturbance in iron metabolism. The observation[5] that the presence of sugar in the diet causes pellagra symptoms to appear more regularly in rats may have some significance in this connexion, as Whipple, Hooper, and Robscheit[13] observed that the fasting anaemic dog was able to regenerate red cells and haemoglobin more readily than the animal fed with sugar. Sure, Kik, and Smith[14] have observed a distinct lowering of the red blood cell count in vitamin B_2 deficiency, and we have also observed the same in this laboratory.

COMMENTARY

The statement that clinical and experimental pellagra is the result of a simple deficiency of the dietary factor, vitamin B_2, has passed into current literature. The above analysis of the existing evidence indicates, however, the inadequacy of this assumption. On the other hand, the suggestion that pellagra is caused by a simple iron deficiency in the diet appears to be untenable in view of Goldberger's and of our own experiments. It is considered probable that pellagra is a complex syndrome arising from an association of various factors, in which the deficiency of an antipellagra factor (Goldberger's P-P factor), which is possibly, but not necessarily, identical with the growth-promoting vitamin B_2, is the main but not the sole factor. Thus, iron might be one of the limiting factors, especially so far as depilation is concerned. Preliminary experiments, carried out in conjunction with L. Mapson, indicate that a balance between vitamin B_2 and other dietary factors might be involved in this question, and that vitamin B_2 may play a part in a particular phase of iron metabolism.

Finally, it is considered that, instead of presuming the identity of the two factors involved in the definition[1] of vitamin B_2 as the "factor in the vitamin B complex other than the antineuritic, which promotes growth and prevents dermatitis in rats," the terms vitamin B_2 and antidermatitis (antipellagra ?) factor should not be used interchangeably, as has been hitherto the practice. Though the terms vitamin B_1 and vitamin B_2 might appear to

indicate some relationship between the two, it may be mentioned that so far they appear to be both chemically[12] and physiologically unlike.

I wish to express my thanks to Sir F. Gowland Hopkins for his interest in this article.

MÉNIÈRE'S DISEASE*

BY

W. S. THACKER NEVILLE, M.D.DUB., F.R.C.S.ED.

HARROGATE

For many years it was taken for granted that Ménière's disease was due to haemorrhage into the labyrinth. This misconception was due to a faulty reading of Ménière's original paper, in which there is no mention of this condition. He described the material found in the labyrinth of his well-known case as being composed of reddish plastic lymph. Alexander of Vienna considers that Ménière's patient suffered from leukaemia complicated by a leukaemic haemorrhage into the labyrinth. Escat thought that Ménière's disease occurred only in arterio-sclerotics, and ascribed the paroxysmal attacks to an intermittent spasm of the internal auditory artery, and the apoplectiform attacks to haemorrhage.

The exclusion of labyrinthine haemorrhage as an etiological factor placed this disease in a less formidable light, for haemorrhage from one intracranial blood vessel implies the possibility of haemorrhage from another, secondary to arterio-sclerosis and high blood pressure. But haemorrhages, arterio-sclerosis, and high blood pressure are absent in Ménière's disease. The vertigo due to spasm of the cerebral arteries in patients with arterio-sclerosis must be distinguished from the vertigo of Ménière's disease in which tinnitus and deafness are prominent symptoms.

INTRACRANIAL CAUSES

The rejection of haemorrhage and arterio-sclerosis as causes of this disease was followed by many theories and, naturally, by as many treatments. Thornval, a recent writer, considers that the main disturbance is in the medulla oblongata. Charcot (1874) and Dandy (1928) put forward the view that there was a lesion of the auditory nerve and not of the semicircular canals. Charcot recommended division of the nerve, and Dandy divided the nerve in nine cases with a resulting cure. Aboulker thinks that the syndrome is due to pressure on the nerve from a collection of fluid around it—that is to say, to an encysted meningitis or hypertension of cerebrospinal fluid in the lateral cisterna. He consequently does a decompressive trephine behind the mastoid, with or without incision of the meninges. Babinski, and, later, Blake, must have had the same idea, as they treated their patients by lumbar puncture. Quix also believes that this disease is due to intracranial hypertension, which acts on the otoliths via the ductus endolymphaticus instead of on the nerves. Kobrak also subscribes to this theory of an intracranial origin. According to his view the trouble is localized behind the labyrinth mainly in the cisterna pontis, and the increased pressure is transferred to the labyrinth via the porus acusticus or saccus endolymphaticus. He thinks that the excess of fluid is caused by an irritation of the choroid plexus or is due to a transudation resembling a circumscribed oedema of the skin. Kobrak uses atropine, pilocarpine, and adrenaline in examining his patients to find out whether the syndrome is associated with a vagotonic or sympathicotonic condition.

INTRA-AURAL CAUSES

The other theories to be considered all agree that the origin is intra-aural rather than intracranial. Thus Witmaack is of the opinion that toxins produced by a catarrhal condition of the middle ear diffuse into the labyrinth via the windows, and so produce an intralabyrinthine hypertension. Quincke believes that the symptoms are due to an angioneurotic oedema of the labyrinth, which brings about an increase in tension of the endolymph. According to Portmann the hypertension originates in the labyrinthine blood vessels. He calls this hypertension of the labyrinth "glaucoma of the labyrinth," and considers that Ménière's syndrome is closely connected with vasomotor phenomena, and hence with sympathetic equilibrium. He believes that the vertigo is caused by a vaso-constriction of the blood vessels of the labyrinth, while tinnitus and deafness are produced by vaso-constriction of the vessels of the cochlea. This vaso-constriction elsewhere would produce pain, as in frostbite or Raynaud's disease. The sign of labyrinth disturbance is vertigo, just as the sign of a diseased cochlea is tinnitus. This vaso-constriction disappears after a sympathectomy, the consequence of which is a vaso-dilatation of the blood vessels of the labyrinth. He also considers that the constriction of the blood vessels may be caused by adrenaline. Portmann does not know whether the vascular stasis produced by vaso-constriction acts directly on he nerves or, as the result of an increase of pressure, on the semicircular canals. With the idea that vertigo was due to an increase of pressure in the semicircular canals he opened the saccus endolymphaticus after performing a mastoid operation without opening the antrum. On the supposition that vertigo was purely a vasomotor reaction he performed a perivascular sympathectomy on the common and internal carotid arteries, and injected drugs which inhibited the sympathetic system, attempting to cause peripheral vaso-dilatation by hot baths. Halphen, on the same grounds, applied cocaine (Bonain's solution) to the sphenopalatine ganglion, and stated that this led to the disappearance of the vertigo after an hour or two, due, presumably, to the inhibition of the sympathetic system. Lermoyez recommended liquor trinitrini in cases of suspected spasm of the internal auditory artery. Amyl nitrite and benzyl benzoate have also been recommended. Muck agrees with Portmann in that he has found his vaso-constrictor nasal reflex present in Ménière's disease. This indicates, according to Muck, the presence of an angiospastic condition of the auditory artery. He has successfully treated five patients with a meatless diet.

FAULTY WATER METABOLISM

Finally, Dida Dederding and Dr. Mygind of Denmark have originated a theory which solves all these problems. They definitely state that the symptoms of Ménière's disease are due to increase of pressure in the semicircular canals, which produces vertigo and deafness by displacement of the stapes. They attribute this increased

* Read before the Darlington Branch of the British Medical Association on March 19th, 1931.

pressure to a faulty water metabolism, which allows water to collect intracellularly, resulting in subcutaneous infiltrations, overloading of the fluid in the labyrinth, and increase of pressure in the cerebro-spinal fluid. To the well-known signs of Ménière's disease—namely, tinnitus, vertigo, and deafness—they add the attribute of variability of these signs, the variability being due to the amount of water retained at the time. Thus, after exercise sufficient to produce perspiration, or following a decreased intake of water and salt, air conduction and bone conduction improve; while after an increased intake of fluid, air conduction and bone conduction decrease, and the latter may even be absent. Low notes are usually not audible, while high notes are well heard. This shows that the cochlea is intact and that hearing can be saved. In late cases the high notes are lost. These writers find the tympanic membranes retracted as a result of stenosis of the Eustachian tube, and so they look upon catheterization as an essential part of the treatment. The stenosis is caused by waterlogging of the lining mucous membrane. The examination of the labyrinth reveals abnormality of the semicircular canals; nystagmus occurs spontaneously, or it can be induced by the inhalation of amyl nitrite, and the turning chair shows a difference in the direction of right and left after-turning nystagmus. The proof that these patients suffer from a faulty water metabolism is that if 1,000 c.cm. of water is administered, only 400 to 500 c.cm. will be passed in four hours, whereas a normal person will pass the 1,000 c.cm. or more during this period. Furthermore, a patient with Ménière's disease will increase in weight corresponding to the amount of water retained; that is to say, if a patient retains 500 c.cm. he will increase in weight by 400 grams, allowing 100 c.cm. for loss through the skin and lungs.

A haemocritic test also shows that in a normal person the blood becomes diluted half an hour after intake of water and regains its normal concentration an hour later, while in a waterlogged patient with Ménière's disease there is no alteration in the dilution of the blood. A waterlogged patient also shows a loss of haemoglobin, the haemoglobin being about 73 per cent. The third proof offered is that an intravenous injection of salyrgan (1 c.cm.) causes diuresis, which commences immediately and lasts two days in a patient with Ménière's disease, while in a normal person the diuresis lasts one day, and there is a decreased output of urine on the second day. In certain patients with only tinnitus and catarrhal otitis disordered water metabolism has been found. These cases can be recognized by noticing an alteration from hour to hour in the perception of low tones or in the air conduction.

TREATMENT

The treatment of Ménière's disease, based on this theory, consists in diminishing the intake of fluid so that the patient loses weight and is actually thirsty. For dietetic purposes fruit and vegetables are considered to be fluid. One also must promote the loss of water by carbonic acid, fir needle, and mud baths, and by the Scotch douche, by exposure to the carbon arc up to one hour three times a week, and by massage. Diet must be salt-free. Local treatment consists in catheterization of the Eustachian tube. The drug treatment in this Danish school is unimportant. Like others they treat the acute attack with atropine, but have found ergotinine also useful. An injection of salyrgan is followed up by a long course of calcium-diuretin; while calcium, ovarian, and thyroid extracts are also used.

I myself have had great success in employing a salt-free diet with a decreased intake of fluid. I have also used a drug (in a few cases) which has been investigated by Berggren—namely, bulbocapnin (Merck). This drug is as valuable in Ménière's disease as ephedrine is in asthma. My patients take one tablet (0.1 gram oral tablet) a day, and this is sufficient to prevent vertigo, while the acute attack is treated by a hypodermic injection (0.1 gram hypodermic tablet), which will almost at once relieve the patient.

MINERS' NYSTAGMUS

BY

W. J. ROCHE, M.B., M.CH., D.O.OXON.
D.O.M.S., D.L.O.

The following investigation favours the theory that defective illumination is the major factor in the causation of miners' nystagmus.

I have investigated the same seam in two pits which are about a mile apart; they are steam-coal pits. In Pit A 0.303 per cent. of the workers are on compensation for nystagmus; in Pit B 1.27 per cent. are on compensation. I have examined the men who are working on the day shift in both pits: suffering from nystagmus—Pit A, 26.25 per cent.; Pit B, 41.42 per cent. In both pits the greatest incidence is among colliers, but there are many more acute cases in Pit B than in Pit A.

Comparison of Conditions

	Pit A	Pit B
Number of men employed ...	1,330	1,230
Number of oil lamps	550	520
Number of 1-c.p. electric lamps	804	770
Depth of seam	1,500 ft.	1,530 ft.
Average thickness of seam ...	4 ft. 2 in.	5 ft. 1 in.
Mechanically handled	100 %	100 %
Barometric reading	23.35	23.43
Analysis of Air		
Carbon dioxide	0.25 %	0.14 %
Methane	0.78 %	1.63 %
Oxygen...	20.62 %	20.35 %
Nitrogen	78.35 %	77.87 %
Hygrometer	68° F	73.75° F.
Analysis of Coal		
Moisture	0.6 %	0.5 %
Ash...	3.6 %	3.0 %
Volatile matter	14.3 %	15.5 %
Fixed carbon	81.5 %	80.8 %
Sulphur	0.53 %	0.84 %
Phosphorus	0.042 %	0.077 %
Quantity of air	1,000 c. ft. per miner	4,920 c. ft. per miner
Velocity of air	17 ft. per min.	122 ft. per min.

The only differences of any importance in this comparison are the depth of seam, the amount of methane, and the velocity of the air. It is nearly as difficult to work in a 4-foot seam as it is in a 3-foot seam, because in both seams the worker has to perform his duties in the reclining and semi-reclining positions. The amount of methane in either pit is so slight as to be of no importance. An increase in the velocity of air means more dust.

A comparison of the reflecting power of the coal faces in the two pits shows a very distinct difference. I am indebted to J. H. Shaxby, D.Sc., physicist and physiologist of the University of Wales, for his co-operation in taking photometric data and making the following comments on reflection and minimum candle power considered necessary to ensure macular vision.

It was noticed that the face of the coal of the same seam in two pits differed appreciably in the size of the facets of the fractured surface. In Pit A these facets are relatively large, and reflect light moderately well; in Pit B they are much smaller, and give the face a more uniform but a duller appearance. The difference seems to be accentuated by the smaller fragments which result from the cuttings of Pit B sticking to the cut surface and increasing its dullness. It was decided to measure the effective reflecting power of the seam in the two pits at the working face, and for this we used a specially made small photometer, which was worked by the illumination of an ordinary electric collier's lamp of 1 candle power.

The instrument consists of a tube about six inches long, in which is mounted a small Lummer-Brodhun cube. Light from the coal face to be examined passes directly through the middle strip of the cube, while light from the lamp falls on the cube from a lateral aperture, and is reflected to the eye from the outer parts of the cube. A simple eyepiece aids observation of the cube. The field of view thus consists of a central strip illuminated by the reflection from the coal face, and areas on either side illuminated directly by the lamp. The light from the latter is subdued and made diffuse by a window of opal glass in the side aperture of the photometer, and over this window slides a neutral absorbing "wedge," fitted with a scale defining its position relative to the centre of the window. By adjusting the setting of the wedge the field is made equally bright in both parts. The fractional amount of light transmitted by the wedge is known for each point on its length. The fraction transmitted by the opal glass window is determined once for all. Thus, from the setting of the wedge the relative amounts of light falling on the instrument from the coal face and from the lamp are determined, and, knowing the distances of the lamp from the coal and from the photometer, it is easy to calculate the reflecting power of the coal.

The data obtained in this way in the two pits work out as follows:

Percentage Reflecting Powers (Averages)

	Pit A	Pit B
	Per cent.	Per cent.
Freshly cut face	15.0	12.0
Slip	15.0	7.5
Roof (dry)	6.3	7.5

In the darkest parts of the face in Pit A the reflecting power fell to 12 per cent., while in one place, where the comparatively large facets of the coal caught the light, it rose to as much as 38 per cent. The reflection from the floor was never more than 2½ per cent., and was usually much less than this in both pits.

The impression gained by general inspection of the coals from the two pits is thus borne out by measurement; perceptibly more light is reflected in Pit A than in Pit B under the same conditions of illumination. As has been stated, Pit A shows relatively much less miners' nystagmus.

It is of interest to calculate the strength of illumination necessary in a coal mine to ensure that the miner will use macular vision. The borderline between photopic and scotopic vision is given by the most trustworthy estimates as corresponding to a field of brightness about 0.0073 millilambert. It is presumably necessary, in order to ensure central fixation, to put a premium on the use of cones rather than rods by giving a brightness well above this borderline. If we assume that double the value is sufficient, and take the millilambert as the brightness of a perfectly diffusing reflecting screen under an illumination of 0.93 foot-candle, we find 0.0136 foot-candle to be required with such a screen. In a coal mine with average reflecting power 10 per cent. we shall then need 0.136 foot-candle, with a reflecting power 5 per cent. 0.272 foot-candle.

Thus, if the miner's lamp is to be 3 feet from the working face, it needs to be of intensity 1.2 or 2.4 for the two reflecting powers considered. If the working distance is 4 feet, the necessary candle power is about 2.2 or 4.4 respectively. It appears, therefore, that lights of less than 4 candle power cannot give an illumination from the coal face sufficient to ensure the employment of central vision.

It will be noted that the light reflected from the slip in Pit A was 15 per cent., whereas in Pit B it was only 7.5. A great amount of the coal in these pits is cut on the slip, and the miner is absolutely dependent on the reflected light to do his work, so in one pit the illumination from the slip was twice as good as in the other pit. In both these pits it takes about twenty minutes before the eyes are dark-adapted; there is no doubt about the fact that the worker must use the periphery of the retina for his work. Colliers and repairers suffer more from this condition than any other underground workers. I suggest that the reason is that their work is difficult form work, and the periphery of the retina was never intended to do seven hours' form work at a stretch.

Miners' nystagmus, like shell-shock and telegraphists' cramp, is a neurosis; there used to be thousands of telegraphists working under the same conditions, yet only some developed cramp; during the war thousands of men fought under the same conditions, yet only some developed shell-shock. We have all a certain amount of reserve nervous energy; some have much more than others. When all one's reserve nervous energy is exhausted a nervous breakdown follows. It is very similar in miners' nystagmus; the reserve nervous energy in the periphery of the retina is used up. In favour of this theory is the fact that all miners suffering from nystagmus complain of twilight blindness; the nervous breakdown in this disease manifests itself in inco-ordination of the eye movements, etc.,

It was thought that when the electric lamp was introduced nystagmus would cease, but it has increased in the proportion of 3 to 1. I will endeavour to suggest why this is the case.

1. The increase in illumination has been from 0.5 candle power in the flame lamp to 1 candle power in the present electric lamp; the increase is not sufficient.

2. *The increase in glare with the 1 candle-power lamp* as compared with the flame lamp is at least one hundred times. This is a great disadvantage.

3. Many men who had latent nystagmus when working with flame lamps developed acute nystagmus when they changed over to electric lamps, because of the increase in glare.

Why is it that nystagmus never occurs in house-coal pits, brown stone mines, or iron mines? Because the

illumination is better, and there is less absorption of light from the working areas

Depending on the distance of the lamp from the coal face, the worker may only have 1/500 to 1/2000 of a candle power with which to perform his work The ideal lamp is the cap lamp, it develops as much as 6 candle power the worker directs his light upon the portion of coal face on which he is working, it ensures macular vision, and there is little annoyance from the glare of other men's lights

RECOMMENDATIONS

1 The ideal illumination is by the cap lamp, many men object to them owing to the discomfort

2 Where cap lamps will not be worn, a hand lamp of not less than 3·9 candle power should be introduced, with frosted prismatic glass with a slight greenish tint The prismatic glass will mean that pillar shadows will be absent the frosted glass with a slight tint will diminish glare There are two lamps, with which I have done experimental work, which I consider are very good —the 3·9 candle power Oldham lamp and the 4 candle power Ukalit lamp These lamps at the end of the shift should not diminish by more than 1 candle power

3 Plain glass electric lamps should not be permitted underground owing to the marked glare

4 An opaque shade should be worn on the back of every lamp by men going to and returning from the coal face as the glare is a source of great annoyance to those following

5 Where possible flood illumination should be used at coal faces

6 Men returning to work after an attack should be employed in the afternoon shift, as they will then leave the pit in the dark, and they will have the maximum amount of daylight when at work, also they will have their week ends free

A detailed account of my investigations on nystagmus will be found in the April number of the *British Journal of Ophthalmology*

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

NEEDLES IN THE OMENTUM

The following is an unusual history of a foreign body in a patient, and appears to justify a description of the case

An unmarried woman aged 22 was sent by her dispensary doctor into this hospital for treatment for abdominal pains These pains were irregular and intermittent and of a stabbing character—they affected her mostly when she was walking or turning in bed She was unable to remember their first onset but was positive she suffered from them as long as she "could remember" and recently they were getting worse and made things very uncomfortable for her She had been operated on two years previously in New York for these pains "which she was informed were due to appendicitis and had her appendix removed but she suffered from similar pains after the operation She returned home to this country over twelve months ago

On admission her temperature and pulse rate were normal and manual examination revealed nothing abnormal other than a vague tenderness over the left iliac region this coupled with marked discomfort revealed on movement and the history suggested symptoms to justify a laparotomy

I opened the abdomen through a medial incision below the umbilicus The appendix had been removed In the pelvis I found a small mass of omentum slightly adherent to the posterior surface of the left broad ligament This was found to contain a needle, the eye and point of which were completely covered by rust On continuing investigations I found two other needles in the upper part of the great omentum and another in the gastro hepatic omentum—all well ensheathed by part of the omentum which resembled fibrous tissue The needles were on an average 1¼ to 1½ inches long and only in one case was the eye present—rust had reduced each one to half its proportions

It was obvious that these needles had been in the abdomen many years I sent for the girl's mother, but she could not remember hearing her daughter complain at any time that she had swallowed a needle, but she confirmed her history of having had pains in the abdomen since an early age I concluded, therefore, that the patient had swallowed the needles in her early days at school or possibly elsewhere, and that they had been present in the abdomen for perhaps fifteen or sixteen years Where they perforated the alimentary tract it is impossible to say, and I was unable to find any adhesions except those in the omentum, which were altogether apart from any viscus The patient left hospital perfectly well in fifteen days

The deductions from this case are obvious, but I may mention I had not the facility of an x-ray apparatus at the time

Limerick County Hospital

CONGENITAL INTRACRANIAL ANEURYSM

The account given of this condition by Reid and Gleave in the *Journal* of March 14th (p 445) prompts me to place on record two cases seen in the past few years

CASE I

A man aged 24 complained of occipital headache and pain in the back of the neck on the day following a water polo match There were no local or general signs to indicate an intracranial origin for these pains Having been in contact with a recent case of encephalitis lethargica he was kept under observation for ten days No further symptoms or signs developed, the pain gradually subsided and finally disappeared He returned to work feeling well About three weeks later he had a sudden seizure while at work and a few minutes afterwards he was seen lying on his left side curled up in an attitude of general flexion He was extremely irritable and his breathing was deep and stertorous He resisted all attempts at examination There was a paresis of the right side of the face The clinical picture closely resembled meningitis but this was excluded by the rapidity of onset He was taken to hospital and died the same night without regaining consciousness

A necropsy revealed a subarachnoid haemorrhage from a ruptured aneurysm of the right middle cerebral artery The greater part of the haemorrhage was recent but there was an older clot close to the aneurysm suggesting an earlier leakage which had presumably occurred when he first complained of headache The Wassermann reaction was negative, and he was in good health previously

CASE II

In December 1929 a single woman aged 20 had a fit, followed by headache and vomiting which lasted a day She returned to work but complained of occasional headaches On the evening of March 20th 1930 she had another seizure which lasted forty five minutes She was seen by her doctor, who noticed that she had ptosis of the right upper eyelid and a dilated right pupil she was sent to hospital On admission she was dazed but was able to reply to questions A minute or two later she had another seizure in which she was comatosed with cyanosis of the face stertorous breathing, and frothing at the mouth The coma deepened and she died fifteen minutes later The Wassermann reaction was not known

At necropsy there was a large subdural haemorrhage over the entire right cerebral hemisphere extending down the front of the medulla The haemorrhage was recent and occurred from a small saccular aneurysm situated at the termination of the right internal carotid artery Near the aneurysm was a small hardened clot resulting from earlier leakage.

This clot was localized and pressed on the adjacent brain substance, producing an area of softening about half an inch in diameter.

Both these patients were young and apparently healthy, without signs of general arterial degeneration. The cause of the aneurysm in both cases can probably be attributed to a local congenital deficiency of the arterial wall. The initial symptoms in both cases were due to a limited leakage from the aneurysmal sac, and the terminal haemorrhage was sudden, copious, and not brought on by any unusual physical stress.

DAVID GLASS, M.B., B.CH.
Municipal Hospital, Middlesbrough.

Reports of Societies

DIABETES AND PREGNANCY

A meeting of the Obstetrical Section of the Royal Society of Medicine was held on June 19th, with the president, Sir EWEN MACLEAN, in the chair.

Dame LOUISE MCILROY, Miss GLADYS HILL, and Dr. PILLMAN WILLIAMS made a communication on diabetes and pregnancy, with a record of seven cases. They stated that the literature on the subject, previous to the discovery of treatment by insulin, was out of date. Many more cases showing that treatment gave very successful results, and that diabetes was not so dangerous when pregnancy took place, were ... consists of a tube about six inches long, ... ere carefully inv... panied a small Lummer-Brodhun cube. Professor Browne emphasized the value of a ... titative estimation of the anterior pituitary hormone ... urine in diagnosis of doubtful cases of vesicular ... the dose of insulin, as variations occurred in the activity of the pituitary. Excessive activity of the pituitary might also account for the apparently low threshold for glucose seen in some instances, such as in acromegaly. He agreed that insulin had revolutionized the treatment of diabetes in pregnant women, but he laid stress upon the importance of adjusting the diet to the requirements of the individual case. Reliance must not be placed merely upon the effects of insulin injections with a more or less uncontrolled diet. Mr. EARDLEY HOLLAND referred to the large number of cases at the London Hospital. He contrasted the treatment of Caesarean section and sterilization with those cases delivered normally at the Royal Free Hospital. General anaesthesia he considered dangerous in diabetes because of its effect upon the pancreas. Spinal anaesthesia with Caesarean section was to be advised unless the labours were abnormally easy. In the latter cases sterilization could be carried out some weeks after delivery by means of local infiltrations of novocain.

INVERSION OF THE UTERUS

Professor F. J. BROWNE showed the specimen of a uterus from a fatal case of acute puerperal inversion of the uterus in a woman, aged 29 years, with one previous child. The labour was attended by a midwife and was uncomplicated, but was followed by post-partum haemorrhage. Inversion of the uterus suddenly occurred spontaneously twenty-five minutes after delivery, and was accompanied by extreme shock. Treatment was immediately instituted to counteract the collapse before, and ... on arrival of, the obstetric assistant. The patient died ... illumination ... the placenta was separated or the uterus replaced. ... other pit. ... men showed complete inversion with the ovaries ... minutes before ... cession. No cause was found to account for ... doubt about th... periphery of the ... RAWLINS described two cases of chronic ... repairers suffer ... me uterus. In one there was a fibroid with ... underground ... ous degeneration, and inversion was complete. ... their ... mother, where a fibroid was also the cause, the patient ... suffered from severe dysmenorrhoea. Removal of the tumour and replacement was effected in both cases, and recovery was complete. Dr. MCCULLAGH said that he had published an analysis of the literature of cases of inversion of the uterus in 1925, and found that of 233 recently recorded, 200 were puerperal and 33 due to tumours. Half of the cases were in primiparae. Shock occurred in 50 per cent. of the patients, and one-third died in a few hours. When associated with a tumour, replacement might be postponed for some days after removal in order to prevent sepsis. Dr. NIXON described a case where the uterus inverted three-quarters of an hour after a normal delivery. It was replaced partially, and ten days later completely, by Aveling's repositor.

Professor BROWNE made a communication on the value of the pregnancy reaction of Zondek and Aschheim in diagnosis and prognosis of chorion-epithelioma, and showed a specimen of a uterus removed by operation from a woman, aged 37, 3-para, who had suffered from continuous bleeding and vomiting for two and a half months. The uterus was about the size of that of a twenty-eight-week pregnancy ; a mole was removed manually. Later, the patient returned to hospital on account of bleeding ... the curettings were negative. The Zondek-Aschheim test was positive on her third admission for haemorrhage, and panhysterectomy was successfully performed. The uterus showed a rounded area of chorion-epithelioma. The reactions were negative six months later. The reaction was of value if positive, even when the curettings appeared

mole. In five cases of vesicular mole in University College Hospital two patients developed chorion-epithelioma, an incidence of 40 per cent. The incidence was usually stated to be 5 per cent.

URETERIC LESIONS

At a meeting of the Edinburgh Obstetrical Society held on June 10th, with the president, Dr. H. S. DAVIDSON, in the chair, Dr. DUNCAN M. MORISON read a paper on ureteric lesions as a cause of abdominal lesions, and on ureteritis or ureteral stricture.

He said that ureteral stricture was a condition which had been only comparatively recently recognized as a definite clinical entity. The pathology was still uncertain. As proved by corrective treatment many cases of apparently obscure abdominal pain were due to ureteric lesions. The zones of the ureter most frequently affected were the nodes or physiological sites of narrowing—namely: (*a*) the pelvo-ureteral junction; (*b*) where the ureter crossed the iliac vessels; (*c*) the transvesical portion; and, in women, (*d*) where the ureter was associated with the broad ligament. Two types might be differentiated—the congenital and the acquired. The congenital type, due to some developmental error, was frequently characterized by a simple localized narrowing without any intramural thickening. The acquired form was apparently secondary to some primary focus of infection, such as tonsils, teeth, prostate, cervix, etc. It might also be induced by certain forms of repeated severe physical exertion—for example, by hammer-throwing. The earlier phases of a ureteritis were associated with local hyperaesthesia of the overlying mucosa, any stimulation of which readily produced ureteral spasm. The initial stage of the infection did not give rise to any appreciable reduction of the ureteral lumen, but later, as intramural changes became more evident, localized zones of narrowing occurred at the affected sites. Due to the intermittent attacks of spasm, and later to the progressive diminution of the ureteral lumen, there ensued an increasing interference of urine conduction and the formation of stasis within the renal pelvis. The condition required attention apart from the discomfort arising directly from the affected portion of the ureter, since there was, in addition, a mechanical hindrance to renal elimination, with consequent adverse effect on the general body metabolism. The rapidity of the destructive process would depend on the site of the lesion. As a general rule, a low ureteritis would take longer to effect renal damage than would a ureteritis at the pelvo-ureteral junction. The lumen of the ureter at the affected site rarely showed marked contraction, hence the term "ureteral stricture," commonly applied, was inaccurate, except in a few instances where a definite fibrous stenosis was present simulating the condition more frequently met with in the urethra. It was probably due to this inappropriate term that misdirected criticism had arisen.

The patient usually presented a mild degree of toxaemia—namely, sense of lassitude, loss of mental acumen, headaches, nervousness, irritability, etc. The local symptoms might be grouped as follows: (1) if attacks of vague pain were complained of in either kidney angle, or laterally below the costal margin, attended by nausea or sickness and occasionally by a dull ache just below and external to the umbilicus, it was probable that examination would reveal a ureteritis of the pelvo-ureteral junction; (2) if pains were referred to the inguinal region a lesion at the pelvic brim was suggested; (3) groin pains without bladder symptoms would point to a broad ligament source; (4) a supra-pubic ache associated with attacks of urinary frequency usually indicated involvement of the ureter at or near its transvesical portion. If, as frequently occurred, a patient had more than one portion of the ureter affected, there was a corresponding combination of the above symptoms. The attacks of pain were commonly described as dull, persistent, and aching in character, and were frequently likened to a toothache. The attacks might last from one to several hours. The pain was gradual in onset, reached a marked degree of intensity, then slowly subsided. At the period of intensity or most marked ureteral spasm there was very commonly a sense of renal discomfort indicating a damming back of urine in the renal pelvis. The pain was not induced by exercise, but fatigue or excessive exertion tended to bring it on. Patients frequently complained that they were wakened in the early hours of the morning by the pain, and that relief was only obtained by rising and walking about for a short time. It might be inferred from this that in the recumbent position the ureter was relatively more extended, and that the slight tension due to this irritated the localized inflammatory area within the ureteral wall. There might be intermissions from pain for days, weeks, or months. As a ureteritis favoured stasis in the upper urinary tract it was frequently complicated by (1) chronic or relapsing pyelitis, and (2) calculus formation. In the successful treatment, therefore, of these two conditions, it was essential that the primary contributing factor was not overlooked.

Since the symptoms might closely simulate those of the chronic appendix and disease in the pelvic organs, differential diagnosis was not easy. The absence of bladder symptoms in all but the transvesical lesion, together with a usually completely negative urine, tended to make any pathological condition of the urinary tract unlikely. A cystoscopic examination would fail to detect the lesion if ordinary straight ureteral catheters were employed, unless the degree of ureteritis was sufficiently marked to render a stenosis evident. By such means, therefore, only a small percentage of lesions would be detected, and the majority missed due to inadequate diagnostic measures. A positive diagnosis might be placed on the following findings: (*a*) the presence of residual urine in the renal pelvis; (*b*) calibration of the ureter by a "bulbed" bougie, noting mechanical resistance to the passage of the bulb or "hang" on its withdrawal, and the local induction of pain and its character; (*c*) reaction pain—if, following instrumentation, there is a reproduction or an exaggeration of the pain previously complained of. Varying amounts of residual urine were to be found in the renal pelvis in cases of long-standing ureteritis, but in the more recent types, where ureteral drainage was still adequate, there was usually none. In the earlier stages reliance had to be placed on calibration. By the employment of "bulbed" bougies the entire length of a ureter could be readily palpated and any altered zone detected. Since the normal ureter resembled an elastic tube, its walls could be painlessly distended to an appreciable degree, but should a segment of this tube be rendered somewhat rigid by inflammatory changes, it would show some resistance to dilatation and the process induce local discomfort. Thus a developed sense of touch and the history given by the patient would determine the location and type of a ureteritis. In doubtful cases, if the pain produced during or following the examination was not similar in character and position to the previously experienced pain, the ureter might be dismissed as a possible factor. Treatment consisted in a course of progressive ureteral dilatation till a size of "bulb" bougie No. F. 12 could be easily tolerated. By this means the attacks of pain were alleviated, and since

better ureteral drainage was achieved there was a corresponding decrease of stasis within the renal pelvis, permitting improved kidney elimination, with consequent benefit to general health.

Dr. J. R. CAMERON read a paper on intracranial injuries in the newborn and their relationship to breech delivery. To illustrate his paper he showed six beautifully dissected specimens of skulls from babies who had died from intracranial injury either at or soon after breech delivery. He also described in detail the birth record of these cases, and made an attempt to correlate the clinical management with the intracranial damage. The technique of dissection was also carefully gone into, and the various anatomical factors involved in the production of these injuries were discussed.

Dr. W. P. KENNEDY described a case of streptococcal infection of the uterus complicating pregnancy in which the case history and post-mortem findings were carefully reported.

ASSOCIATION OF CLINICAL PATHOLOGISTS

The fifth summer meeting of the Association of Clinical Pathologists was held in the pathological department of the General Infirmary, Southport, on June 20th, with Dr. E. CRONIN LOWE in the chair.

Dr. J. G. GREENFIELD, in a paper on the clinical pathology of the cerebro-spinal fluid, drew attention to the value of the Queckenstedt phenomenon in the diagnosis of sinus thrombosis. A fall of pressure with absent or only slow return of the fluid to a higher level on compression of one jugular vein was a strong indication of thrombosis on that side. He emphasized the importance of flakes of preformed fibrin in the withdrawn fluid as an indication of subdural haematoma. In cases of chronic disease Dr. Greenfield considered that a routine examination demanded a total and differential cell count, tests for the presence of globulin by the Pandey and Nonne-Apelt reactions, estimation of the total protein, and the performance of one of the colloidal reactions—the ones he favoured being the bi-coloured guaiac reaction and the Wassermann reaction. He pointed out that a Wassermann reaction stronger in the cerebro-spinal fluid than in the blood, or a positive Wassermann reaction in both fluid and blood, disappearing on treatment more rapidly from blood than from the spinal fluid, both indicated a syphilitic infection of the parenchymatous rather than the meningeal type. He said that in the investigation of acute cases the cerebro-spinal fluid was a good culture medium, and that in meningococcal meningitis incubation of the fluid overnight would often give a profuse growth of the organism before it had appeared upon artificial culture media. The percentage of chlorides in the spinal fluid he regarded as dependent upon the level in the blood, and its determination was of the utmost value in the diagnosis of tuberculous meningitis. The sugar percentage was low in all acute infections ; acetone was present in many cases of hyperemesis and cyclical vomiting ; the urea level was greatly raised in uraemia.

Dr. S. C. DYKE stated that in his opinion, although it was satisfactory to find the bacillus in making the diagnosis of tuberculous meningitis, it was quite possible to establish a firm diagnosis without demonstrating it. The presence or absence of a fine clot, the total and differential cell count, the chloride, sugar, and protein percentages, and the presence, absence, or excess of globulin, made it perfectly possible to say that a cerebro-spinal fluid was or was not from a case of tuberculous meningitis. Dr. Dyke drew attention to the fact that the chloride level of the spinal fluid was lowered not only in pulmonary but also in peritoneal pneumococcal infections. Dr. HUGH SMITH stated that he had found that if a few threads of cotton-wool were added to fluid from cases of tuberculous meningitis and the fluid centrifuged the tubercle bacilli tended to adhere to the threads, and could then be readily demonstrated by staining in a slide preparation. Dr. G. W. GOODHART said that, while ready to believe that it was possible to diagnose tuberculous meningitis without demonstrating the bacillus, he thought it was desirable in every case to do so ; were this not done, and should the case subsequently recover, the diagnosis would inevitably be called into question. Dr. F. B. SMITH stated that he had seen a case of pituitary tumour in which the urea content of the spinal fluid had been high, and asked if other members had had any such experience. Dr. GREENFIELD said that in some cases of cerebral disease, notably in post-vaccinal encephalitis, he had found a high urea content. Dr. H. SMITH briefly recorded a case of aseptic meningitis after spinal novocain anaesthesia, with recovery.

Dr. G. W. GOODHART reported five cases of megaloblastic anaemia not of the pernicious type. All these cases showed a progressive anaemia with high mean diameter of the red cells ; in every case, however, it was possible to demonstrate that they were not of pernicious type by the plotting of the Price-Jones curve. In all of them this curve, although shifted to the right of normal, was symmetrical, the cells showing an even deviation about the mean. The first case at post-mortem showed numerous polypoid masses in the small intestine ; the second resembled pernicious anaemia in every way except in the symmetrical nature of the Price-Jones curve and in the fact that the bone marrow at post-mortem was not found to be hyperplastic ; in the third ascites and jaundice were present ; the fourth followed upon generalized glandular enlargement vigorously treated by deep *x*-ray therapy. The last case improved with iron. In none was there any result from treatment with liver or desiccated stomach. The fifth case was one of sprue, and responded to liver treatment. Dr. A. F. S. SLADDEN drew attention to the Arneth count in the diagnosis of pernicious anaemia. He stated that in all typical cases there was a shift to the right. Dr. F. B. SMITH referred to a case of anaemia in a child of 15 months showing megalocytosis in which liver proved effective.

Dr. S. MILLER demonstrated a blood transfusion apparatus. He drew attention to the confusion caused by the coexistence of the Moss and Janssky classifications of the blood groups, and asked the opinion of the meeting as to the best form of classification. Mentioning the value of auto-transfusion in cases of ruptured ectopic pregnancy, he asked if transfusion was advisable in cases of bleeding from duodenal ulcer. Dr. DYKE said that the association had already adopted the international classification of the blood groups on the basis of the A and B agglutinogen content of the red cells ; this he considered to be the only way of escape from the existing confusion in nomenclature. In his experience transfusion in gastric bleeding entailed no risk of restarting the haemorrhage, and citrated blood appeared to be actually haemostatic. He then gave an account of two cases of transfusion in universal agglutinators. The serum of both patients agglutinated the cells of all prospective donors (irrespective of group) and even their own red cells ; this agglutination took place only in the cold, and was reversed at incubator temperature. In both cases the transfusion had been followed by a severe reaction which, however, had been readily controlled by adrenaline and morphine. Dr. Dyke pointed out that "auto" or "cold" agglutination was no contraindication to transfusion.

Reviews

BREAST FEEDING

In her book on this subject,[1] Dr MARGARET EMSLIE has succeeded in collecting most of the useful information which has accumulated during the renascence of breast feeding. At one time breast feeding was almost universal, but during the latter years of the last and the first few years of this century it had fallen into comparative desuetude, largely owing to the temptations dangled before the eyes of motherhood, not only by the enterprise of commercial minds, but also by medical enthusiasts, who believed that they had found a complete and satisfactory substitute for breast milk. The teaching and experience of welfare centres where large numbers of healthy children have been kept under observation has proved that the women of this country are not so decadent with respect to the mammary function as has been generally supposed, and this discovery has brought many a child back to the breast who would otherwise have been condemned to the bottle.

Unfortunately, the principles and practice of breast-feeding have not been well taught at maternity hospitals where the majority of midwives receive their training, nor are most of the teaching midwives adequately equipped for imparting a knowledge of breast feeding to others. Another factor that militates against the practice of breast feeding is that the best trained maternity nurses—that is to say, those who have had a full nurse's training—have had no opportunity of learning details of breast feeding in the hospitals where they have been taught. And again, ordinary domestic nurses who have been educated at nursery training schools, with one or two notable exceptions, have had *no opportunity* of acquiring practical experience in the natural method of feeding. With so many adverse factors and so few countervailing arguments, it is scarcely to be wondered at that breast feeding is so largely replaced by artificial methods. The publication of Dr Emslie's little book, with its many attractions and its breezy optimism, comes at a timely moment. The author is highly practical in her recommendations. She indicates the advantages of breast feeding without belittling or disguising the difficulties. She devotes a good deal of attention to a matter which is often considered incompatible with success—namely, flat retracted, or inverted nipples. We rather question whether the method of manipulation which she describes for curing the third mentioned condition is quite so simple or so effective as she suggests, or indeed so valuable as the older method of drawing out the depression by means of suction.

Dr Emslie is whole heartedly in favour of infrequent feeding. She would apparently prolong the intervals even beyond four hours, which in the opinion of competent authorities is the limit to which the intervals should be extended. It is possible that a compromise between extremes might be reached satisfactorily if it were agreed to feed the new born infant, at a time when its stomach is incapable of holding more than an extremely small quantity of milk, at intervals of three hours, and as the stomach develops, to increase the intervals gradually, even up to Dr Emslie's proposed limit provided that the required total could be thus obtained in the twenty four hours without overfilling of the stomach.

One of the least satisfactory parts of the book, as it appears to us, lies in the fact that it affords little help in the management of cases in which there is insufficient milk to satisfy all the needs of the child without supplementation. The use of the "test feed" in this, as well as in cases in which there is obviously a superabundant supply of milk, and even in those cases in which there is apparently the correct amount, is so abundantly justified that we are rather surprised that Dr Emslie pours cold water on its advantages. We believe we are correct in stating that at the present time at Queen Charlotte's Maternity Hospital the test feed is employed in all cases, with most excellent results, and it is probable that this practice will extend to other teaching centres.

In this little book there are chapters on the anatomy and physiology of the breast, on the establishment and maintenance of breast feeding, on difficulties in breast-feeding, and on weaning. Each one of these has its value.

MODERN CONCEPTIONS IN CARDIOLOGY

The demand for a second edition of *Recent Advances in Cardiology*,[2] by Dr C. F. T. EAST and Dr CURTIS BAIN has given the authors an opportunity to revise certain sections of their admirable book. In the construction of a work dealing with recent advances in any branch of medicine various difficulties must be faced. Not only must new conceptions and new methods find adequate expression, but sufficient fundamental material must be included to provide continuity and a logical basis for more recent work. In this respect the present book is excellently compiled. Further, in this second edition important improvements have been made. The revision of the chapter on angina pectoris has resulted in an admirably concise account of this condition, and additions to the chapters on fibrillation and flutter, and on the radiology of the heart and aorta, are very definite improvements. The rewritten account of cardio-vascular syphilis gives a well balanced view of the pathology and clinical features of the disease, but the very debatable technique of arsenical treatment is discussed too briefly. There must be many clinicians who have felt that the sudden deterioration in a cardio vascular syphilitic was the result of too early arsenic injections, and who have wished that the preliminary course of iodide and mercury medication had been extended to six weeks or more. The addition of a note on Averza's syndrome gives greater completeness to this section.

Although the present work is concerned essentially with cardiology, it seems strange that peripheral vascular diseases should be almost entirely omitted. Considerable space is devoted to recent work on the circulation rate and to the physiology of the peripheral circulation, while thrombo angutis obliterans, Raynaud's disease, and peripheral arterio sclerosis leading to gangrene are scarcely mentioned. It may well be held, taking a broad view of cardio vascular disorders, that no book on recent advances should omit some discussion of these clinical entities, whatever else is excluded or cut down. This is especially the case in view of the modern French work on peri-arterial sympathectomy and acetylcholine and the still more recent German production of muscle extracts, which bid fair to assume a very important position in cardio vascular therapeutics. However, in its sphere this second edition of *Recent Advances in Cardiology* is pre eminently sound and well co-ordinated, and it is certain that neither the cardiologist nor the general practitioner anxious to acquaint himself with modern conceptions in cardiology can afford to neglect it.

[2] *Recent Advances in Cardiology.* By C. F. Terence East, M.D., F.R.C.P., and C. W. Curtis Bain, *M.C.*, M.B., M.R.C.P. Second edition. London: J. and A. Churchill. 1931. (Pp. x + 353, 62 figures, 10 plates. 12s. 6d.)

EDEN AND HOLLAND'S "MIDWIFERY"

The sixth edition of Dr. WATTS EDEN'S admirable *Manual of Midwifery* appeared in 1925, under the editorial supervision of Mr. EARDLEY HOLLAND, and was noticed at some length in these columns. As it has been out of print now for more than a year the issue of a new edition[3] will be welcomed by students and practitioners alike. Mr. Holland remarks in the preface that "apart from important discoveries in female sex physiology there have been during the past six years few, if any, fundamental advances in the science and art of obstetrics; but there has been a general move forwards all along the line, and the standards of teaching and practice are steadily rising." The attention focused of late on midwifery in its practical and theoretical aspects has led to a great deal of revision and the rewriting of several sections. Most of the old illustrations have been redrawn and produced in half-tone, and many new figures are included. At the end of each of the nine parts into which the book is divided will be found a "Guide to further reading," for the benefit of those who are preparing for higher examinations, as well as for those engaged in the active practice of obstetrics; and what amounts to a new section on the newborn child is contributed by Dr. K. H. Tallerman.

The other important changes in the present edition are enumerated by Mr. Eardley Holland in his general preface. Among these we may note the incorporation of recent work on the ovarian hormones and the influence of the anterior pituitary body; the adoption of the name "pre-eclampsia" to denote the usual toxaemic "albuminuria of pregnancy"; the expansion of the section on narcosis and anaesthesia; and the bringing together of occipito-posterior positions of the vertex as a complete unit in the section on abnormal labour. Management of labour with contracted pelvis has been rewritten, as has ante-natal supervision, which now finds a place in the section on normal pregnancy. Under disorders associated with pregnancy the section on diseases of the heart and circulatory system has been entirely recast in the light of modern cardiology, and additions have been made to the paragraphs on chronic nephritis and diabetes mellitus. Foetal asphyxia has also been rewritten, and is now subdivided into intrauterine asphyxia and post-partum asphyxia, or asphyxia neonatorum. So convinced is Mr. Holland of the potency of "droplet infection" during the puerperium that he does not hesitate to state his opinion that "were simple measures universally adopted by doctors and nurses to prevent its occurrence, the incidence of puerperal infection would show a remarkable decline." In the section on the maternal mortality of childbirth the statistical tables have been brought up to date.

Generally speaking, the work of revision has been carried out most judiciously, and a fresh lease of popularity may be predicted for this well-balanced guide to the practice of midwifery.

MEDICINE AND EDUCATIONAL PROBLEMS

Early last year a conference of junior public school masters was held at Harrow. The addresses then delivered have now been published under the title of *Harrow Lectures on Education*.[4] The book is edited by Mr. T. F. COADE, an assistant master at Harrow, who has divided it into two parts, the first dealing mainly with the significance of the chief divisions in the school curriculum and their several contributions to education, and the second dealing with the subject of religion in connexion with education. Many of these essays contain a great deal of wisdom, and some of them, especially in the second part, are full of truth and beauty. It is perhaps a pity that the division of the book was not into three parts instead of two, for there are three addresses by members of the medical profession which differ (though not in the same way) from the others with which they are associated in Part I. These are: "The need for a more modern school hygiene," by Dr. George Murray Levick; "The subject of sex, with special relation to public schools," by Dr. Douglas White; and "The psychological understanding of the adolescent," by Dr. H. Crichton-Miller. Each of these contributions is very valuable and suggestive. Dr. Murray Levick is concerned with four chief factors, which he declares are deficient in almost every school—diet, atmospheric hygiene, time-table, clothing. His discussion of these factors is sufficiently detailed, is very practical, and is based upon a large experience. He is of the opinion that "hygiene in every boarding school should be supervised by a competent specialist in that subject." The other two articles have some affinities with one another, and should certainly be read together. Possibly that by Dr. Crichton-Miller is, on the whole, the most important in the book. To the schoolmasters to whom it was addressed it must have seemed a courageous utterance, and it is certainly a true one. To study the elements of modern psychology is the duty of every schoolmaster, and to understand his own as far as possible is an essential preliminary to an attempt to appreciate that of those who are under his charge. "In any case the schoolmaster should understand the principle of suggestibility, with its reverse manifestation in the rebel. He should understand the place of fantasy in the mental life of the young, and most of all he should be able to trace the mechanism of compensation." There is much more in Dr. Crichton-Miller's article than is indicated by this quotation. Indeed, both his contribution and that by Dr. Douglas White are of real importance, and cannot but be of great interest and help to all those who may be concerned with the subject to be discussed in the Medico-Sociological Section of the British Medical Association at Eastbourne this month: "The need of education in questions of marriage and sex."

ALTERATIVE TREATMENT

The idea embodied in Professor DETERMANN'S book *Umstimmung als Behandlungsweg*[5] is alteration as an objective in medical treatment. Many writers, in various fields of medicine, contribute to the discussion of this idea, and Dr. Weichart, in his introductory chapter, suggests that opinion is swinging from an endeavour to kill the germs of disease to an endeavour to put the organism in a position to resist them. He points out that tuberculosis, for example, is a specific disease for which specific treatment has proved inadequate, and has given place to a method of cure by non-specific remedies, often of a physical nature. The chemical and biological basis of true alterative treatment is defined; the examination of individual function and pathology is stressed, and the importance of individual adaptation and choice of the appropriate time and period of treatment. Thus in chronic rheumatic cases treatment may well consist of daily hardening measures, combined with periodical intensive or pyretic treatment—for example, by yatren. In subsequent chapters the factor of organic alteration is discussed in connexion with the vegetative system and

[3] *A Manual of Midwifery*. By Thomas Watts Eden, M.D., C.M., F.R.C.P., F.R.C.S., and Eardley Holland, M.D., F.R.C.P., F.R.C.S. Seventh edition. London: J. and A. Churchill. 1931. (Pp. xii + 718; 389 figures, 9 plates. 21s.)

nutrition, with infective, nervous, respiratory, digestive, circulatory, and other categories of disease. There are also sections on the alterative effect brought about by climate and weather, irradiation, electrical and hydrological treatment, as well as by endocrine medicaments and drugs.

ORGANIC MICROANALYSIS

Dr. PREGL'S *Quantitative Organic Microanalysis*[6] is a book describing practical methods of performing analytical determinations with quantities of material which are *microscopical in comparison* with those ordinarily used. No other method but microanalysis is available for ascertaining the composition of many of the substances which exert important functions in life or which occur as products of biological activity. Pregl is one of those who have done most to render these methods practicable and trustworthy. His account of the general scheme of procedure and the details applicable to special cases is accordingly of high value. It is a book of remarkable interest, containing accounts of a great number of rare devices with which to overcome the difficulties inherent in the *nature of* the work. The translation by Fyleman has been so ably performed as to be a welcome gift to English chemists, particularly those who follow biological chemistry.

NOTES ON BOOKS

Everybody's Boswell[7] is a judiciously abridged edition of the complete biography, small enough to handle and carry easily. Of many interesting features perhaps the most noteworthy is the inclusion of the tour to the Hebrides, a quaint and delightful episode that deserves to be better known. There is an amusing incongruousness in the picture of Dr. Johnson—far from Reynolds and Mrs. Thrale—losing his spurs in the Atlantic surges and bowing over the hand of Flora Macdonald; yet something in the Gaelic temper pleased his mood. It was a heroic undertaking for an old man with a cumbrous frame, beset by nervous and organic maladies, to set out on a fatiguing and dangerous journey in the eighteenth century to island places not yet very easily accessible. The volume owes much of its attractiveness to Mr. Shepard's illustrations, which strike an instant recognition in the fancy

Various articles by Dr. EDWIN BEER of New York, which have been published in medical journals during the last twenty-five years, have now been brought together in a single volume[8] and grouped according to the subject-matter. The topics dealt with are gastro-intestinal conditions from the surgical point of view; pathological states of the liver, kidney, bladder, ureters, and prostate; an account of the history of surgery of the spleen; operative treatment of tumours and metastases of the spinal cord; and miscellaneous subjects, mostly surgical in nature, as well as reports of clinical cases. Indexes to the subjects dealt with, and also to the names of authors mentioned in the text, facilitate reference to the varied contents of this large volume.

Some of our readers may like to know of the publication of a reprint from the fourth edition of Sir ISAAC NEWTON'S *Opticks: or a Treatise of the Reflections, Refractions, Inflections, and Colours of Light*.[9] Professor Albert Einstein supplies a brief foreword, and there is an introduction by Professor E. T. Whittaker. The original title-page of the fourth edition (1730) is reproduced.

Volume i of Dr. SOUTHWELL'S report on the Cestoda of British India was noted in these columns on November 22nd of last year (p. 872); the second and final volume has now been published.[10] This deals with the majority of forms found in man and the domestic animals, as well as many of less direct medical interest. It discusses, among other worms, the two human taenias, echinococcus and hymenolepis. Southwell does not accept the generic name echinococcus, and states that the cyst is most frequently found in bovines (observers elsewhere find that sheep, pigs, and horses are more frequently infected). He regards the dwarf hymenolepis of mice as identical with *H. nana* of man, and gives preference to the name *H. murina* for both forms. The volume is essentially a faunistic and systematic one, but it is a valuable addition to our literature on the tapeworms.

[6] *Quantitative Organic Microanalysis.* By Fritz Pregl, D.Sc., Ph.D. Second English edition. Translated from the third revised and enlarged German edition by Ernest Fyleman, B.Sc., Ph.D., F.I.C. London: J. and A. Churchill. 1930. (Pp. xiv + 237, 51 figs. 15s.)

[10] *The Fauna of British India, including Ceylon and Burma.* Edited by Lieut.-Colonel J. Stephenson, C.I.E., M.B., D.Sc., I.M.S. (ret.). Vol. II. *Cestoda.* By T. Southwell, D.Sc., Ph.D., A.R.C.S., F.R.S.E. London: Taylor and Francis. 1930. (Pp. ix + 262; 355 figures. 15s.)

PREPARATIONS AND APPLIANCES

ASEPTIC VAGINAL EXAMINATION

Dr. C. CHAPLESON, F.R.C.S.Ed. (resident surgical officer, County and City of Perth Royal Infirmary), writes.

To overcome the difficulty of traversing the contaminated vulva in examining obstetrical cases I have devised a form of cuff made of glove rubber. This consists of a conical tube 12 inches long, 2 inches in diameter at the narrow end, and 3 inches in diameter at the wide end, which is flanged with similar material (*Fig. 1*). The narrow end is invaginated (Fig. 2), and the hand passed in at A, gripping the point of

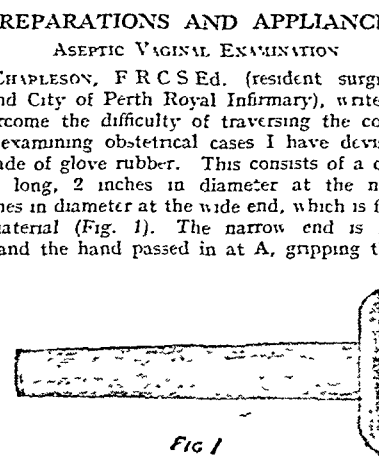

FIG 1

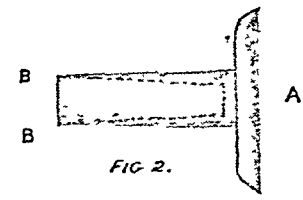

FIG 2.

invagination at B B. The hand so covered is passed just *inside the vulva and the invaginated portion evaginated into* the vagina by the examining hand, this finally passing completely sterile through the narrow end of the cuff into the cavity of the uterus, having touched neither vulva nor lower vagina. This cuff can easily be carried dry, sterilized and powdered in a package with a pair of gloves.

AN ANTACID

Normo-gastrine (Messrs. Burgoyne, Burbridges and Co. Ltd.) is an interesting new type of antacid. The preparation is composed of silicate of aluminium with 20 per cent. of added excipient, and is a light, insoluble powder devoid of taste. It acts as a buffer to strong acids but has little action when the acidity is less than *p*H 4·0. The purpose of the preparation is to antagonize any excessive gastric acidity and to bring the gastric juice to its normal degree of acidity without risk of destroying the pepsin by rendering the gastric juice alkaline. The makers claim that their preparation gives rapid relief in hyperchlorhydria. It is based on sound physiological principles, and deserves careful clinical investigation.

CENTENARY OF THE LEEDS SCHOOL OF MEDICINE

[FROM OUR CORRESPONDENT IN LEEDS]

Though lectures on anatomy were delivered by the first William Hey towards the end of the eighteenth century, and more systematically by Mr. C. T. Thackrah in the early years of the nineteenth, it was not until the year 1831 that the Leeds School of Medicine was actually founded, but it is the oldest of the bodies which are now happily united in the University of Leeds. It preserved its independent existence till the year 1884, when it was incorporated with the Yorkshire College, for the college which was established in 1874 under the name of the "Yorkshire College of Science" had by this time introduced a Department of Arts and had shortened its name while widening the scope of its work. The Yorkshire College now consisted of the Department of Science, Technology and Arts, and the Department of Medicine, the instruction in chemistry, biology, and physics being undertaken by the teachers at the "College." Strengthened by this, the Yorkshire College was able to approach the Victoria University and ask to be admitted as the third of its constituent colleges in the affiliated university which already was composed of two colleges—the Owens College of Manchester and the University College of Liverpool. The association was a very harmonious one, but, for reasons which need not here be discussed, separate charters were given to Liverpool, to Manchester, and to Leeds. There can be no doubt whatever that this disruption has worked for the good of each of the three centres, and year by year the Leeds University is growing in strength and in influence. Nothing has better shown the cordial relationship which exists between the Faculty of Medicine and the other Faculties of the University than the way in which the University as a whole has entered into the celebration of the centenary of the "School of Medicine" which is now the Faculty of Medicine in the University.

CENTENARY CELEBRATIONS

A dinner of the former students of the School was held on the evening of June 30th, at which delegates from the other Universities and teaching bodies were guests. The gathering was a large one, but it had to be brief, as everyone desired to go on to the Art Gallery, where the Lord Mayor, Dr. Hawkyard, was giving an "At home." The official celebration was held on July 1st, when the Chancellor, the Duke of Devonshire, presided over a large congregation of the University. The teaching staff of all departments of the University was well represented, and the Chancellor formally received all the delegates—some fifty in number. These included the Regius Professors of Physic of Oxford and Cambridge, Sir Farquhar Buzzard and Sir Humphry Rolleston. Addresses were then given by the Chancellor and by the Vice-Chancellor, both of whom extolled the courage and faith of the original founders. The Vice-Chancellor gave an interesting account of the development of the School, and spoke very hopefully of greater improvements in the near future. Those who have worked in connexion with the School for many years cannot but regard with the greatest satisfaction the ties which are binding together more and more strongly the Faculty of Medicine with the other Faculties of the University, and the University with the General Infirmary at Leeds, with the Maternity Hospital, and with the School of Dentistry. If in the future further unions with other institutions are amicably and carefully carried out, it will be to the advantage of everyone concerned, and not least to the suffering public and to the students of medicine. In their addresses both the Chancellor and the Vice-Chancellor extended to the delegates a most cordial welcome. Sir Humphry Rolleston and Major-General H. C. R. Hime, late R.A.M.C., a former student of the School, replied. The former, in a charming speech, introduced tentatively and with an engaging show of hesitation what most of his audience regarded as a new word in his reference to the foundation of the school "which to-day we have assembled to *centenarize*." May the writer of these lines express the hope that "centenarize"—clothed in the authority of Sir Humphry—has come to stay!

CONFERMENT OF HONORARY DEGREES

The Chancellor then conferred honorary degrees on the following:

Dr. Arthur Hawkyard, Lord Mayor of Leeds, LL.D. Presented by the Vice-Chancellor.

Dr. Jane Walker, LL.D. Presented by the Vice-Chancellor.

Dr. Alfred George Barrs, LL.D. Presented by Professor Rawdon Veale.

Sir John Bland-Sutton, LL.D. Presented by Professor Dobson.

Lord Dawson of Penn, LL.D. Presented by Professor Maxwell-Telling.

Sir Walter Morley Fletcher, D.Sc. Presented by Professor M. J. Stewart.

Sir Frederick Gowland Hopkins, D.Sc. Presented by Professor McSwiney.

Sir George Newman, LL.D. Presented by Professor Jamieson.

The inclusion of the names of Arthur Hawkyard and Arthur George Barrs in this group of honour has given great satisfaction to the local medical profession, who know the Lord Mayor to be a man of great public spirit and one of the soundest of practitioners, and who recognize in "Barrs"—for initials and titles seem to those who are privileged to know him well to take from his individuality—one of the soundest of physicians, one of the best clinical teachers, and one of the loyalest of friends.

SOCIAL ENTERTAINMENTS

The members of the Leeds and West Riding Medico-Chirurgical Society, of which Dr. Hawkyard happens this year to be the president, entertained the delegates at luncheon. Receptions were given in the afternoon at the School of Medicine, where the extensions, both those which are completed and those in course of being carried out, were of special interest to former students; and at the General Infirmary, where the various departments were shown to the visitors by an able body of stewards recruited from the resident staff and from the students.

A dinner, given by the University, followed by the University ball, brought an interesting day to a successful ending. At the dinner the chair was taken by the Pro-Chancellor, Colonel Tetley, D.S.O. In the toast of "The Foster Parents of the Leeds School of Medicine" a tribute of gratitude and respect was paid to the Royal College of Surgeons of England and to the Society of Apothecaries, for these were the two bodies for whose diplomas the medical students of Leeds, in common with Mr. Bob Sawyer, were wont to study in former days, and they were the first to recognize the School as a place for the instruction of the student. Lord Moynihan, P.R.C.S., and Colonel Samman, Master of the Society of Apothecaries, replied. The former devoted a large part of his speech to commenting on the great heritage which was the possession of the Leeds School, and pointed out the ways in which the present and future generations might try to emulate the great men who had preceded them. Especially he emphasized the demand and the necessity for post-graduate teaching, and the imperative and urgent

need for the establishment of travelling scholarships, so that men might fit themsselves for election to the staff by visiting other schools, learning their methods, and drawing their aspirations from a wide area.

A word of praise is due to those who made such excellent arrangements for the celebrations; everything went smoothly and with apparent ease. To those who were old enough to recall the days when there was but one whole-time professor on the staff—and all were glad to see Professor Birch looking so well and so little changed—the development of the School since 1884 indeed appeared wonderful. But perhaps the most lasting impression left on the minds of those former students who were able to be present was that which sprang from the renewing of old long-lapsed acquaintances and friendships and from visiting the haunts of their youth.

MEDICAL CONGRESSES, 1931

The following congresses and conferences on medical and allied subjects have been announced for the remainder of the year. Particulars are given below in the following order: date, name of organizing body, place of meeting, name of person to whom inquiries should be addressed. More detailed information about these meetings is given from time to time, as it becomes available, in the news columns of the *British Medical Journal*.

July 13-19.—British Social Hygiene Council. London. Secretary of Council, Carteret House, Carteret Street, S.W.1.

July 19-22.—International Congress of the Collegium Oto-Rhino-Laryngologicum. Bordeaux.

July 21-25.—British Medical Association. Eastbourne. Medical Secretary, B.M.A. House, Tavistock Square, W.C.1.

July 22-30.—French Colonial Exhibition (Lectures on Tropical Medicine). Paris. Dr. Robinson, 28, Rue de Ponthieu, Champs Elysées, Paris, VIIIe.

July 26-31.—International Congress of Radiology. Paris. Dr. Ledoux-Lebard, 122, Rue La Boëtie, Paris, VIIIe.

July.—International Congress of Laryngology. Bordeaux.

August 3-8.—International Congress of Industrial Medicine. Geneva. Mr. G. L. Perry, Industrial Welfare Society, 51, Palace Street, S.W.1.

August 3-8.—International Dental Congress. Paris. Mr. A. E. Rowlett, 165, London Road, Leicester.

August 3-8.—International Congress of Photography. Dresden. Dr. R. Luther, Paradiesstrasse, 2, Dresden, A.20.

August 31-September 6.—International Congress of Neurology. Berne.

September 2-19.—International Illumination Congress. Great Britain. Colonel C. H. Silvester Evans, c.o. The Illuminating Engineering Society, 32, Victoria Street, S.W.1.

September 12-17.—International Congress of Tropical Medicine. Amsterdam.

September 13-19.—International Congress of Balneology. Carlsbad. Dr. Edgar Ganz, Carlsbad, Czechoslovakia.

September 14-16.—German Orthopaedic Society. Berlin. Professor Wollenberg, Prager Platz 5, Berlin-Wilmersdorf.

September 14-17.—American Public Health Association. Montreal. Secretary of Association, 450, Seventh Avenue, New York.

September 14-19.—Medical Association of South Africa (British Medical Association). Johannesburg. Dr. B. G. Meile, Medical School, Hospital Street, Johannesburg.

September 21.—Royal Institution (Faraday Centenary). London. Secretary of Royal Institution, 21, Albemarle Street, W.1.

September 21-23.—German Pharmaceutical Society. Vienna.

September 21-23.—German Association for Occupational Hygiene. Nuremburg. Secretary of Association, Platz der Republik, 49, Frankfort.

September 23-25.—Society for the Study of Metabolism and Diseases of Digestion. Vienna. Professor von den Velden, Bambergerstrasse 49, Berlin, W.30.

September 23-30.—British Association's Centenary Meeting. London. Secretary of Association, Burlington House, Piccadilly, W.1.

September.—Pan-Russian Congress of Gynaecologists and Obstetricians. Moscow.

October 1-3.—German Society for Urology. Vienna.

October 14-18.—International Congress of Comparative Pathology. Paris. Dr. Grollet, 7, Rue Gustave Nadaud, Paris, XXVIe.

ROCKEFELLER MEDICAL FELLOWSHIPS

The Medical Research Council announces that, on behalf of the Rockefeller Foundation, it has made the following awards of travelling Fellowships for the academic year 1931–32. These Fellowships are awarded to graduates who have had some training in research work, either in the primary sciences of medicine, or in clinical medicine or surgery, and who are likely to profit by a period of work at a chosen centre in America, or, in special cases, in Europe, before taking up positions for higher teaching or research in the British Isles.

ERNEST THOMAS CONYBEARE, B.Sc., M.B.Lond., Guy's Hospital, London.

GORDON MONCRIEFF DEAN, M.B.Aberd., Department of Surgery, Aberdeen University.

MORRIS HARRIS FINKELSTEIN, B.Sc., M.B.Ed., Department of Bacteriology, Edinburgh University.

OWEN STANLEY GIBBS, M.B.Ed., late Professor of Pharmacology, Dalhousie University, Canada.

EMANUEL MANNIE LOURIE, M.B.Lond., D.T.M., Liverpool School of Tropical Medicine.

ALLAN WILLIAM SPENCE, M.B.Cantab., M.R.C.P., St. Bartholomew's Hospital, London.

CONRAD HAL WADDINGTON, M.A.Cantab., Strangeways Research Laboratory, Cambridge.

KENNETH HAROLD WATKINS, F.R.C.S., Royal Infirmary, Manchester.

The Fellowships awarded to Dr. Gibbs and Mr. Waddington are tenable in Europe, the others at centres in the United States. Dr. Conybeare and Mr. Waddington have been appointed on modified conditions while receiving emoluments from other sources.

ROYAL MEDICAL BENEVOLENT FUND

During the first six months of this year the committee has been called upon to vote grants amounting to £6,349 13s., which is £1,161 3s. 5d. in excess of the amount voted in grants during the corresponding period of last year. Unfortunately, the income received from subscriptions and donations this year does not show a corresponding increase over last year, but a decrease; unless new subscribers will come forward in support of the Fund before the end of this year the committee will be forced to curtail its activities.

All who can are urged to send a subscription to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, W.1.

At the last meeting of the committee twenty-six grants were voted, amounting to £562. The following are particulars of two of the cases helped.

Widow, aged 68, of M.R.C.S., L.R.C.P. Her husband was professor at a medical school in the Near East. It was brought to the notice of the Fund that this lady, who had enjoyed a good social position, with all the ordinary comforts of life, and had lived for many years in a warm climate, had during last winter been living in a bed-sitting room, and had often been unable to afford a fire in her room. Owing to unfortunate investments her income had gradually diminished, until last year she had only £89 to live on. She had to pay 9s. a week for her room, which left only £66 a year for her maintenance, clothes, light, and warmth. Fund voted £36.

Widow, aged 51, of M.B. Husband died abroad last summer at the age of 47, having been in private practice there for twelve years. The Ex-Service League paid the widow's passage money to England. When debts and outstanding expenses have been paid, it is expected that the husband's estate will yield an income of £70. Since the death of her husband the widow has had a severe illness. When she landed in England she had only the clothes which she had travelled back in. The Fund voted £26, payable during the next six months, as it is hoped that when she has recovered her health she will be able to undertake some employment. The Guild has supplied clothes.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

SATURDAY, JULY 11th, 1931

HIGH BLOOD PRESSURE

In 1733 Stephen Hales, who was Rector of Farrington and Minister of Teddington, wrote in his second volume in *Haemostatics*: "I caused a *mare* to be tied down alive on her back," and, "having laid open the left crural artery about 3 inches from her belly, I inserted into it a brass pipe." The blood rose in a tube of 1/6 of an inch in diameter to a height of 8 ft. 3 in. above the level of the left ventricle. By this bold experiment it was proved beyond doubt that a high arterial pressure existed in mammals. Such a direct demonstration was impossible in human beings, and for 150 years after Hales's experiment palpation of the radial artery was the only method by which a physician could estimate the normal and abnormal blood pressure in man, until von Basch introduced the clinical sphygmomanometer in 1883. At Monti's clinic in Vienna von Basch in 1884 made the first systematic investigation of blood pressure. Technical improvements in the construction of sphygmomanometers rapidly followed. Riva Rocci in 1896 and Hill in 1897 adopted the method of circular compression. More accurate readings were obtained by the use of the wider "cuff" which von Recklinghausen employed in 1901. By these methods the systolic pressure alone could be measured; the modern way of estimating the systolic and diastolic pressures by auscultation was shown in 1905 by Korotkow. Since that time the elaboration of instruments in portable form has kept pace with the increasing mechanical ingenuity of the modern technician. Yet the observation of the facts of raised blood pressure and renal disease, and the formulation of the theories to explain these facts, were made and propounded by men who had to rely upon their sense and their senses only.

As a result of his classical investigation on albuminuria, Bright formed the conception of systemic vascular disease which has been the basis of all subsequent work. Looking for an explanation of the cardiac hypertrophy in his cases, he suggested in 1837 that the altered state of the blood in chronic nephritis "so affects the minute and capillary circulation as to render greater action necessary to force blood through distant subdivisions of the vascular system." In 1856 Traube, a pupil of Purkinje, from the clinical observation of the hard pulse, the large heart with its thrusting impulse and loud sounds, and of the signs of renal disease, inferred that there was an elevation of blood pressure directly dependent on a resistance to the flow of blood through the injured kidneys. It was inevitable, therefore, that the attention of numerous workers should be concentrated on these two factors as causes of high blood pressure: the mechanical obstruction of the kidney —the theory put forward by Cohnheim—and the altered quality of the blood. The problems of renal physiology, even now incompletely solved, must then have obstinately obtruded themselves in the way of those trying to elucidate the diverse manifestations of a damaged kidney. The search for the products of a disordered metabolism which might act as pressor substances began. The idea that the kidney was the primarily insulted organ became fixed, until in 1872 Gull and Sutton found that in certain cases the heart was large and the arteries thickened in a group of patients whose kidneys were healthy. They introduced the significant term of "arterio-capillary fibrosis." In his Hunterian Lecture on senile plethora, in 1895, Clifford Allbutt gave an account of four cases of "arterial hyperpiesis" in elderly persons, the state of whose kidneys "was consistent with subsequent good health." From this new fact, that high blood pressure could exist apart from renal lesions, there arose a doubt as to the exact part played by the kidney in the production of hyperpiesis in nephritis. The change of front necessitated new ideas. The kidney could no longer be regarded as the isolated apex of an invisible triangle. The heart, the arteries, and the kidney were regarded as one functional unit, the cardio-vascular renal system, or (in Osler's apt analogy) the pump, the tubing, and the filter.

In his lecture printed in this issue of the *Journal*, Professor John Hay writes: "You must know your man before you tackle his malady." You should also know your organ before you tackle its diseases; and it is this imperfect knowledge of the healthy kidney that has, perhaps, offered the greatest obstacle to research. The blood pressure depends mainly upon the output of blood from the left ventricle and upon the peripheral resistance; of these two factors the latter is thought, and logically so, to be the more important in the causation of hyperpiesis. Nearly one hundred years ago Bright thought that the changed quality of the blood affected the minute and capillary circulation. Twenty-one years ago Clifford Allbutt said that "viscosity is at least a *vera causa* of arterio-fibrosis," adding the pertinent remark that "diffusion and osmosis are universal, and govern the balances of viscosity." One year ago the researches of Harris and McLoughlin led them to the conclusion that viscosity of the blood is a causal or contributory factor in high blood pressure. The part played by viscosity is still unsettled. It seems probable that the increased peripheral resistance, shown by a rise in the diastolic pressure, depends upon a throttling down of the blood stream at the level of the arterioles. But, since Krogh demonstrated the independent activity of capillaries, increased interest has been shown in their possible influence on blood pressure. Lewis, for example, found that constricted capillaries could resist a pressure of 90 or 100 mm. Hg. Kylin, whose work has not been confirmed by all observers in the same field, showed that in the acute nephritis after scarlet fever or tonsillitis

a rise in capillary pressure preceded the arterial elevation and appeared about a week before the albuminuria. Irregularity of the capillary pattern has also been noticed in cases of hyperpiesia by Müller and Hübener, who found also an orderly arrangement of the capillaries in chronic nephritis; the capillary pressure in each of the two types they found to be normal or subnormal. According to Boas, on the other hand, there are two types of hypertension, one with normal and the other with increased capillary pressure; the latter, he suggests, may be associated with general capillary disease, with glomerulo-nephritis as one part of the picture of a generalized disease process. But here again the question is unsettled. Many experiments have shown that obliteration of the kidney vessels alone does not influence the blood pressure.

Out of a vast accumulation of observations, many of them contradictory, it is difficult to say that this or that is *the* cause of hypertension. The numerous terms invented indicate the confusion of thought that exists. And when all is said and done one is left with the main theories proposed during the first half of the nineteenth century—the renal, the arterio-sclerotic, and the vaso-constrictive theory. The view that vaso-constriction, however it may be caused—whether by tissue metabolites, by pressor substances from the breakdown products of protein, by bacterial toxins, or by imbalance of the endocrine system—precedes and determines medial hypertrophy and intimal degeneration appeals to the mind by its logical simplicity. The chief difference in attitude between the modern and the earlier workers is that now both essential hypertension and nephritis are thought to be manifestations of a widespread vascular disorder. This view has been expressed by Geoffrey Evans, who, as a result of his researches, concluded that "diffuse hyperplastic sclerosis shares with chronic nephritis and chronic interstitial nephritis a common etiology."

Perhaps the most important cause of high blood pressure is civilization. We tend to accept disease too complacently. The fitting of fact into theory fascinates. This is healthy, for it stimulates research, but the danger often is that men, instead of seeing the wood, let alone the trees, may concentrate too long on the leaves. The incidence of high blood pressure is increasing. The stress and strife of modern life, with its complicated economic and social structure, is proving too much even for the stoutest arteries. Professor Hay emphasizes the importance of the effect of psychological states in altering arterial tension. Even in sleep there are marked variations. Fear, worry, indulgence in temporal pleasures, anxious striving, are all admitted to be important contributory factors. If Samuel Butler were alive he might suggest that medicines are of no use if the emotions are disorganized, and might support his thesis by pointing out that where there is disharmony between instinctive behaviour, the vegetative nervous system and the ductless glands, vicious elevations of blood pressure are inevitable. The final synthesis of so many facts and theories awaits another Richard Bright.

THE CENSUS FIGURES

The preliminary report by the Registrar-General, Mr. S. P. Vivian, on the 1931 Census of England and Wales was published on July 6th.[1] It is divided into three parts: an introduction by the Registrar-General describing the system employed on April 26th last and the difficulties encountered in the work of enumeration; statistical notes on the findings; and tables, arranged geographically, showing population, acreage, and Parliamentary electors in 1921 and 1931. The figures included in this report are provisional, and relate solely to the numbers by sexes of the population both for the country as a whole and for an extensive series of local areas. This information has been obtained in advance of the main statistical operations by so organizing the procedure as to permit of the simple figures being abstracted locally and summaries rapidly compiled by local registrars for assembly at the Census Office. The figures are subject to confirmation in the substantive Census reports, though, judging by past experience, no material discrepancy is anticipated.

The preliminary returns show that the total population of England and Wales is now 39,947,931, females outnumbering males by 1,670,243. This total is the largest ever recorded, and the areal density it represents—685 persons per square mile—is, with the possible exception of Belgium, far higher than that of any country of which there is record, and much more than double that of most other countries. The 1931 total exceeds the number returned at the census of 1921 by 2,061,232, corresponding to an inter-censal rate of increase of about five and a half per cent. Three striking features brought out by the figures now published are the increase of urban population at the expense of rural districts, the growth of Greater London and the South of England generally, and the enormous decline in the number of births during the past ten years. The total births registered were more than a million and a quarter fewer than in the preceding ten years, and between two and two and a half million fewer than those of the last completely normal decennium, 1901–11. "The full significance of the fall will be but dimly appreciated for many years to come." As a partial set-off against the almost unbroken fall in the birth rate, the deaths registered were more than half a million fewer than those of either of the two preceding decennia. Notwithstanding variations from year to year, the standardized death rate—that is, the rate in which allowance is made for the age distribution of the population—for every individual year from 1921 to 1930 has been lower than the similar rate recorded for any year before 1921.

The figures comprised in the present report are, as we have said, provisional, relating solely to the number and sex of the population, and it is too early to draw any deductions of real importance from them, or to do justice to the many points of interest which emerge.

THE CEREBRAL CORTEX DURING UNCONSCIOUSNESS

By a combined study of the conclusions reached by Pavlov and the clinical studies of Kinnier Wilson, R. L. Worrall[1] has attempted to analyse the underlying physiological mechanisms of epilepsy, narcolepsy, and cataplexy. Pavlov showed that reflexes (" regulated responses to the external world ") are of two kinds—the unconditioned, and the conditioned. Unconditioned reflexes are stable, constant, present from birth, and initiated by stimulation of the lower nervous centres. Conditioned reflexes, which are cortical in origin, unstable, and temporary, depend for their existence on the association of their stimuli with those concerned in producing reflexes of the lower nervous centres. Conditioned reflexes, at first generalized, and differentiating but little between similar stimuli, later become specialized, the action of those allied stimuli which do not coincide with the conditioned stimulus being in time obliterated by the process of inhibition. Pavlov demonstrated further that there is a constant irradiation and concentration of excitation and inhibition around various points of the cortex. Excitation of one cortical region is followed by inhibition at that site, and also in surrounding regions. This type of development of inhibition from excitation, and vice versa, was termed " induction " by Pavlov, following Sherrington's terminology ; it is reciprocal, but inhibition radiates more freely than excitation. Stimulation of one point of the cortex leads to inhibition of the remainder ; this " negative induction " of Pavlov is held by Worrall to be highly significant in the interpretation of certain clinical symptoms. Pavlov asserted that such a spread of inhibition over the whole cortex was the basis of sleep, and Worrall proceeds to argue that other forms of unconsciousness may have a similar neurological basis. He explains unconsciousness in epilepsy on this basis of irradiation and concentration of cortical excitation and inhibition, with their mutual and reciprocal induction, the return of consciousness after a seizure resulting from a concentration of inhibition subsequent to its irradiation ; the briefer the period of unconsciousness in a fit, the more rapid is this ensuing concentration. He agrees with Kinnier Wilson that the epileptic symptoms are probably not due to cerebral vasomotor changes. The focal point of stimulation in fits with convulsive movement is in the motor area of the cortex ; the excitatory process may irradiate to the whole cortex with, in cases of unconsciousness, a mutual negative induction of inhibition over the rest of the cortex. In cataplexy the physiological inhibition of the motor cortex results from an emotional stimulus. It does not extend beyond the motor area, and so the patient does not lose consciousness. Descent of the inhibition to the lower motor centres obliterates their tonic contractile action, and this continues for a considerable time. The patient therefore sinks motionless and spec[illegible] pulse, the la[illegible] recovers the use of his [illegible] and loud sounds, and of the[illegible]. In many cases of [illegible] inferred that there was an elev[illegible]imulation, often with directly dependent on a resistance [illegible] area of the through the injured kidneys. It was inevit[illegible]ordinating fore, that the attention of numerous workers [illegible] concentrated on these two factors as causes [illegible]

[illegible] No. 44, Medical [illegible]

point for efferent impulses to the facio-respiratory muscles by a separate path, giving rise to " involuntary " expression of emotion. For some unknown reason a general process of inhibition radiates then over the whole cortex. Modifications of this mechanism are held by Worrall to explain the occurrence of the transitional types between narcolepsy and cataplexy. Whatever may be the ultimate fate of Worrall's method of approach, this relating of the neurological and psychological standpoints does unquestionably hold out a hopeful prospect for further investigation of the state of unconsciousness.

GUY'S HOSPITAL REPORTS

The second quarterly instalment of the *Guy's Hospital Reports*[1] contains matter of exceptional interest, even for the reader wise enough to let no number of this publication pass without at least inspection of its contents. In 1911 the late Sir Samuel Wilks, in his *Biographical Reminiscences*, recorded the advances in medicine made at Guy's, especially during his teaching career there, by epitomizing the articles in these *Reports* from 1836 to 1885. His pupil and admirer, Sir William Hale-White, continues the analysis, makes it attractive by many personal touches and recollections of the writers, and recalls the admirable obituaries of members of the staff, particularly those written by the late W. H. A. Jacobson and R. Clement Lucas. The present instalment of Sir William's historical article carries the story on to 1895. In the course of it he pays a fine tribute to his contemporary L. C. Wooldridge, who died prematurely in 1889, a genius who " seemed to live in order to throw light on obscure problems," an inspiring teacher who " taught his audience how to think." A second noticeable feature in this number is a series of articles on the less well-known forms of anaemia ; Dr. L. J. Witts, who last year contributed a valuable article on simple achlorhydric anaemia, now supplies two papers, one on the allied condition of late chlorosis, based on eighteen cases ; the other on the syndrome of glossitis, dysphagia, and anaemia, often, but erroneously from a strictly historical point of view, called the Plummer-Vinson syndrome after the two workers at the Mayo Clinic, who collected sixty-nine cases there in 1922, an earlier description having been given by Kelly and Paterson three years before. From analysis of thirteen cases Dr. Witts concludes that the incidence of the syndrome, the anaemia, the digestive disturbances, and the nervous phenomena are very similar to those of simple achlorhydric anaemia and late chlorosis. Dr. R. S. Harrison, who records a case of primary aplastic anaemia, due to a progressive decrease in the power of producing blood, and treated by 105 blood transfusions in four years, divides the cases into three groups: (1) primary, in which no cause can be discovered ; (2) a sequel of other anaemias, such as Addison's pernicious anaemia ; and (3) due to overdosage of x rays, radium, and certain poisons which cause degeneration of the bone marrow. Dr. Hurst, who obviously inspired these articles, gives an account of a woman with severe simple achlorhydric anaemia, following gastro-jejunostomy for a pre-pyloric ulcer, who, after improving under large doses of iron, had an

[1] *Guy's Hospital Reports.* Vol. lxxxi (vol. ii, Fourth Series), No. 2. April, 1931.

acute cerebral attack very similar to lead encephalopathy; though no similar case has been reported, the attack was ascribed to iron poisoning. Mr. W. L. Watt and Dr. Knott, in their article on irradiation and leukaemia, emphasize the importance for successful irradiation treatment of an adequate number of active phagocytes in the patient's blood. Professor G. W. Nicholson writes philosophically, and with a wide outlook on form and structure, Mr. E. W. Sheaf gives his experience of Crile's treatment of acute appendicitis, and Mr. Shaw writes on ocular paralyses in diphtheria.

STANDARDS OF MEASUREMENT

The first number of the new volume of *Nature* (July 4th) is distinguished by a supplement containing the chief part of the Guthrie Lecture delivered to the Physical Society of London by Sir Richard Glazebrook, F.R.S., the theme being "Standards of measurement: their history and development." The eminent physicist has given long attention to the subject of standards, and his lecture provides a remarkable review of their varying history. He begins by commenting on the ancient standards of length, on the Olympic cubit—from which our foot and inch have probably descended—on the Greek foot, the Roman foot, and the British foot. The standard of weight in Sumerian times was the mina, whence came the talent, the Alexandrian talent forming the basis of Greek, Roman, and Western European weights until the advent of the metric system. The development of the pound avoirdupois, complicated by the marc of Cologne, gave Britain the Tower or Mint pound. Troy weight, of obscure origin, had a parallel existence. In the reign of Elizabeth two juries examined and fixed standards, and so established the modern system of weights and measures. It is noteworthy that the first application of science to this subject in Great Britain was due to the Royal Society, and that in France the members of the Paris Academy of Sciences were responsible for the replacement of the old French measures by the metric system. Among those who introduced accuracy to the standards of this country were Graham, Bird, Troughton, Kater, and Dr. Hyde Wollaston, and no survey would be complete without reference to the researches of Miller, Baily, and Sheepshanks when the standards were destroyed by the fire of 1834. Notable events in recent years have been the organization of the International Bureau of Weights and Measures at Sèvres, and the conference on standardization held last year at the Board of Trade to discuss the question of inter-Dominion standards. So far, confidence has been placed in the permanence of a material standard, but since the realization of the fact that a wave-length of light of a given frequency remains invariable, the International Committee of Weights and Measures, at its meeting in 1925, agreed in principle to define the unit of length by means of this natural standard, if a satisfactory method could be devised. With this object in view investigations have been undertaken at the National Physical Laboratory, the Reichsanstalt, and at the U.S. Bureau of Standards. Hence, there is a prospect that a natural standard of length will in time be generally accepted. In electricity transference to natural standards is already taking place. It is clear from Sir Richard Glazebrook's able lecture that the quest for the "absolute" standard is not without a certain romantic attraction, more perceptible to-day, perhaps, than at any other period in the history of the subject.

OBSTETRICS AND CHILD HEALTH IN THE UNITED STATES

In November, 1930, a White House Conference was summoned by President Hoover to consider the possibility of further advances being made in promoting the health of children; some of the papers of obstetrical interest then read are published in the June issue of the *American Journal of Obstetrics and Gynaecology*. This conference was the third of a series, the first being held in 1909 to deal with the problems of the dependent child, and the second in 1919. The first of these had as its outcome the establishment in 1912 of a Children's Bureau of the Department of Labour, while the second was followed by eight important regional conferences, in which discussion of the social and economic status of the child was naturally supplemented by consideration of its health and that of its mother. The conference in 1930 included fifteen main committees, one of which was occupied with questions of medical service. This issue of the *American Journal of Obstetrics and Gynaecology* opens with the address of Dr. F. L. Adair, chairman of the committee on prenatal and maternal care, who comments sadly on the prevailing high maternal, foetal, and neo-natal death rates, and insists that more attention must be paid to educating the public and affording better training for medical practitioners, dentists, nurses, and midwives. He believes that the best plan would be the extension throughout the country of a systematic co-ordination of the work of medical practitioners and nurses, associated with a more adequate training of specialists in obstetrics and gynaecology. Reference is made in this connexion to the setting up of the American Board of Obstetrics and Gynaecology which issues certificates to approved practitioners. Dr. Palmer Findlay, discussing the possibilities of improved undergraduate instruction in midwifery, reports the conclusions reached by this committee. Unification is recommended of the departments of obstetrics and gynaecology in medical schools, and in all hospitals affiliated with and controlled by the universities. The committee also endorsed the recommendation of the American Association of Medical Colleges that 5 per cent. of the total hours required for medical graduation should be devoted to instruction in obstetrics. One subcommittee reported that further development of post-graduate training in this branch of medicine was imperative, while another subcommittee expressed the opinion that "the ultimate solution of the problem of good obstetrics lies, not in the midwife, but in developing a sufficient number of doctors who are well trained in the fundamental principles of obstetrics." Professor J. O. Polak, presenting the report of a subcommittee on prenatal, maternal, and early infant care, advocates the establishment of a nation-wide obstetrical programme, under the auspices of the Federal Government, the State, and the county. This would involve the subsidizing of county hospitals and privately owned rural hospitals as obstetrical centres. It is announced that a full report of the conference proceedings will be published in several volumes.

REFRESHER COURSES FOR SHIP SURGEONS

Following the recommendation of the special committee consisting of representatives of the shipping companies, the Ministry of Health, the London School of Hygiene and Tropical Medicine, the Seamen's Hospital Society, and the British Medical Association,[1] a programme of post-graduate courses for ship surgeons has been formulated, and lectures and demonstrations began on Monday at the Devonport Pathological Laboratory of the Seamen's Hospital Society at Greenwich. The principal objects of the course are to enable ship surgeons to take a series of "refreshers," and for candidates for these posts to receive special instruction in ships' hygiene, Board of Trade requirements, and clinical subjects in their special application to conditions on board ship. The courses of instruction are divided into three parts: (1) ships' hygiene, the Shipping Acts, quarantine procedure; (2) tropical medicine and hygiene; (3) a refresher course in clinical subjects. On drawing up the detailed schedule, it was decided that Series 2 should take place at the London School of Tropical Medicine and the Hospital for Tropical Diseases; that Series 3 should start on July 6th, at the Devonport Pathological Laboratory at Greenwich; and that Series 1 should be held during the autumn. A common room has been provided at the Dreadnought Hospital, immediately opposite the laboratory, for the use of the students, and the authorities are providing food at reasonable prices for the convenience of all attending. The refresher course will comprise a brief outline of modern methods of clinical diagnosis and treatment, with special regard to the limitations which obtain at sea and to the equipment at the disposal of a ship surgeon.

SIR HENRY THOMPSON

The *Urologic and Cutaneous Review*, which is published in St. Louis, contains in the issue for June, 1931, an interesting account of Sir Henry Thompson, written by Mr. George Buckston Browne, who worked with him as a private assistant for fourteen years. Sir Henry Thompson was a self-made man who came of an artistic stock on his mother's side, for his maternal grandfather was Samuel Medley, who painted the well-known portrait group of the founders of the Medical Society of London. His father kept the village shop at Framlingham in Suffolk, and both his parents were uncompromising Unitarians, who were so strongly opposed to science that their son was unable to begin his medical studies until comparatively late in life; it was not until he had attained the age of 33 that he became house-surgeon to Sir John Eric Erichsen, who had then just been appointed to the office of surgeon at University College Hospital. At the conclusion of his term of office Thompson went into private practice, and had the good fortune to marry Miss Kate Loder, who was making a handsome income in London as a teacher of music. "Come to London," she said; "I can keep the fire burning." They came, took a little house in Wimpole Street, and bought a private hansom cab. As surgeon to the Marylebone Infirmary Thompson saw much of old men as patients, and from his experience with them he gained the Jacksonian Prize at the Royal College of Surgeons in 1859 for his essay on "diseases of the prostate." The prize brought him Sir James Clark as a patient, and Sir James had long been in Royal favour. Clark caused him to be consulted by Leopold, King of the Belgians (uncle to Queen Victoria) who had suffered much from a stone in the bladder. He was operated upon successfully, and Sir Henry Thompson soon acquired the largest and most lucrative genito-urinary practice, certainly in this country, and perhaps in the world. A man of versatile mind, he was an ardent supporter of cremation; his pictures appeared on the walls of the Salon in Paris and the Royal Academy in London; he was a great collector of Chinese ware, and was well known as one of the gourmets of the last quarter of the nineteenth century. The paper is well worth reading, for it is written from personal knowledge. We learn from it that Thompson never performed a prostatectomy, and Mr. Buckston Browne says: "The late Mr. A. F. McGill of the Leeds General Infirmary in 1889 was the first surgeon who ever systematically removed all that can be removed of an enlarged prostate. I was the first to follow his example in London, and on March 6th, 1893, before the Medical Society of London, with Sir Jonathan Hutchinson in the chair, I read two cases and showed one very successful one, of prostatectomy. I have never had occasion to retreat from what I then said, that the operation, useful and justifiable as it often is is too dangerous to be made a routine operation." The same issue of the *Review* contains an account of Mr Buckston Browne, illustrated with an excellent portrait likeness.

WINGFIELD ORTHOPAEDIC HOSPITAL

We have from time to time had pleasure in commenting on the progress of the Wingfield Orthopaedic Hospital and of the clinics in Oxfordshire, Berks, and Bucks which are connected with it. The annual report for 1930 is a record of much good work. In looking through the list of operations we note with interest that the greatest number (85) under any one heading are classed as sequestrotomies, etc., the next largest figure being 48 tendon transplantations. These figures are evidence of the prevalence of infective bone disease and of anterior poliomyelitis. In the medical report it is also stated that there is a small but steady decrease in the severity of deformities and diseased conditions owing to the earlier general recognition of disease. Were it not for the long waiting list no doubt the decrease would be greater still. Like some other hospitals the Wingfield feels the strain of the call upon its services in industrial and transport accidents, owing to its equipment for the efficient treatment of fractures. The committee is fortunate in having the support of such a generous benefactor as Sir William Morris of Oxford.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

[1] See *British Medical Journal*, April 18th, 1931, p. 676.

ACTIVITY OF VITAMIN CONCENTRATES

The importance of an adequate vitamin supply in the diet is now recognized, not only by the medical profession, but also by the general public, and therefore a steady demand exists for palatable preparations containing vitamins in concentrated form. The preparation of such concentrates is rendered very difficult by certain outstanding properties of vitamins: these are, their occurrence in very small quantities, their ready destruction by many chemical processes, and their special liability to lose activity on keeping. These properties are all adverse to the preparation on a commercial scale of vitamin concentrates that will still be active when they reach the public.

Our knowledge of vitamins is of recent growth, and seven years ago, when their chemistry was very imperfectly understood, there was so great a tendency for optimism to outstrip probability in the claims made regarding the activity of commercial products that this *Journal* arranged for tests to be made of the activity of certain widely advertised vitamin preparations. The results of these tests, and of similar investigations carried out in America, were unsatisfactory, for they showed that the makers had in most cases greatly overestimated the activity of their preparations. (Coward and Clark, *British Medical Journal*, January 6th, 1923; McCollum and Simmonds, *Journal of the American Medical Association*, 1922, lxxviii, 1953.) Since that date many advances have been made in our knowledge of vitamin chemistry—for example, the manufacture of vitamin D has been achieved; this can now be produced in any quantities desired, and since it is relatively stable no great difficulty in this case attends the manufacture of concentrates. Similarly, the substances grouped under the term vitamin B can be concentrated in a fairly stable form. On the other hand, the preparation of stable concentrates of vitamins A and C still encounters very serious obstacles, for although concentrates of both these vitamins can be made which are fairly stable under laboratory conditions, yet it is a matter of great difficulty to ensure continued stability when these concentrates are mixed with other foodstuffs. Hence it is not easy to prepare for the market a mixture of vitamin concentrates in a palatable form which is reasonably stable.

It is of great importance to the medical profession to know whether such preparations can be relied on or not, for they are extensively used with the object of preventing deficiency diseases. The problem of practical importance is not whether the preparation was originally made from a highly active vitamin concentrate, but whether this is still active when it reaches the patient.

In view of these facts the Council of the British Medical Association considered it advisable to give authority for tests to be made to estimate the activity of preparations advertised as containing these vitamins. Unfortunately, such tests are very laborious and consequently expensive, and the investigation was therefore limited to a few preparations issued by firms of repute, upon whom the medical profession might reasonably rely. The manufacturers were notified of the proposed inquiry and gave their assent to it. In each case samples were bought in the open market.

METHOD OF TESTING

The tests were conducted by Dr. K. H. Coward in the Pharmacological Laboratory of the Pharmaceutical Society. Reasons of space prevent publication of the full reports, but the following are some of the essential points. The tests were as follows:

Vitamin A.—Rats were fed on a diet deficient in this vitamin until growth ceased; then a measured quantity of the commercial preparation was given to one group of rats, and the effect on growth compared with the effect of varying quantities of standard cod-liver oil given to other groups. The activity of the preparation as compared with the standard cod-liver oil was thus determined.

Vitamin D.—Rats were fed on a rachitogenic diet for three weeks; one group was then given the preparation, and two other groups were given different quantities of standard irradiated ergosterol. After ten days all the animals were killed, and the ulnae and radii were examined. The potency of the preparation in healing rickets, as compared with irradiated ergosterol, was then measured.

Vitamin C.—Guinea-pigs were fed on a basal diet deficient in this vitamin, and were given, in addition, a dose of either the preparation to be tested or of orange juice. After fourteen days the animals were killed, their jaw bones were removed, and the roots of the incisors examined histologically for signs of scurvy. The degree of scurvy was rated at none, moderate, or severe. The activity of the preparation in terms of orange juice was then measured.

RESULTS OF TESTS

The chief conclusions regarding the commercial preparations tested are as follows:

I

A preparation of cod-liver oil with malt extract, advertised as containing vitamins A, B, and D.

This preparation was tested for content of vitamins A and D three months after it had been purchased. The tests showed that 15 mg. of the preparation possessed a vitamin A content equal to that of 5 mg. of a good sample of cod-liver oil, and a vitamin D content of 40 units per c.cm., whereas the content of a good cod-liver oil is 100 units per c.cm.

The preparation contained 21 per cent. fat, and hence the vitamin activity of the fat is as regards vitamin A 1.6 times, and as regards vitamin D twice, that of a good sample of cod-liver oil.

II

A food advertised as containing vitamins A, B, C, and D.

This preparation was tested for vitamin C content one month after purchase. A daily dose of 5 grams did not prevent scurvy in guinea-pigs. A daily dose of 10 grams produced partial protection against scurvy, and the protective effect was slightly less than that produced by 3 c.cm. of orange juice.

A teaspoonful of this product weighs 10 grams, and therefore these figures indicate that a daily dose of six teaspoonfuls is equivalent in antiscorbutic potency to approximately one-quarter of an orange. The dose recommended by the makers for children is up to one teaspoonful three times a day. This report was referred to the manufacturers. They pointed out that the preparation had a specific gravity of 1.4, and therefore the report implied that 7 c.cm. of the preparation was slightly less effective than 3 c.cm. of orange juice, a conclusion which

was in very fair agreement with their claim that the product contained antiscorbutic vitamin equivalent to half its volume of fresh orange juice.

III

A preparation advertised as containing vitamin C in addition to vitamins A, B, and D.

A daily dose of 10 grams of this preparation afforded no protection to guinea-pigs against scurvy. This unsatisfactory report was confirmed by an independent test in another laboratory, which was arranged by the makers of this preparation. The makers have therefore withdrawn the claim that this preparation contains vitamin C, and their advertisements have been amended accordingly.

IV

A food advertised as containing vitamins A, B, C, and D.

This was tested for the potency of its vitamin A and C content one or two months after purchase. The vitamin A potency of the preparation was found to be equivalent to one-quarter of its weight of a good quality cod-liver oil. The preparation was nearly four times as heavy as cod-liver oil, and hence the vitamin A activity of a teaspoonful of the preparation was nearly equal to that of a teaspoonful of cod-liver oil. Tests for vitamin C activity gave negative results. A daily dose of 5 grams of the preparation produced no measurable antiscorbutic action, and the same result was obtained with a daily dose of 10 grams.

Copies of the reports were forwarded to the manufacturers of this preparation, who in the course of their comments on them said:

"Whilst we do claim that —— contains vitamin C, and, therefore, has certain antiscorbutic properties, we have never asserted that it is in itself efficient as a cure for scurvy, but rather that its vitamin C content renders it of definite value in a prophylactic sense. . . . A perusal of the report in question has led us to devote a deal of study to this subject, and we are pleased to advise you that we are taking steps to modify substantially the process of manufacture of ——. We believe that as a result of these modifications the efficiency of the product will be increased."

DISCUSSION

The substances tested were not a random sample of vitamin preparations; they were chosen as products upon which the medical profession might be expected to place reliance. On the other hand, they were tested for their content of the most easily destroyed vitamins—namely, A and C.

The results can be considered fairly satisfactory as regards vitamin A, for both products tested had an activity similar to that of cod-liver oil. This may appear to our readers to be a somewhat low standard, but, owing to the ease with which vitamin A is destroyed, this standard is difficult to attain.

The three tests for vitamin C were very disappointing, for two were completely negative. We may point out that there is no reason to doubt that highly active concentrates of vitamin C had been put into these preparations, but, unfortunately, they had disappeared during the process of manufacture, a result that is extremely difficult to avoid. Biochemists have advanced our knowledge of vitamin chemistry very greatly during the last decade, but the difference between producing results on a laboratory scale and on a commercial scale is

Concentrates of most of the vitamins can be produced in the laboratory, and they are fairly stable if kept under ideal conditions. In the case of commercial preparations it would appear that their content of vitamin A only equals that of cod-liver oil in the more favourable cases, and in the case of vitamin C it would appear to be a very difficult problem to produce a commercial preparation which contains any of this vitamin. Evidently it is difficult for the manufacturing chemist even to equal the natural sources of vitamins A and C; and, therefore, it is still advisable for the medical profession to exercise caution before abandoning cod-liver oil and orange juice as sources of these vitamins in infant diets.

We would again emphasize the fact that the preparations tested were chosen as being the most likely to yield satisfactory results, and probably a random selection would have provided far worse results. We have every reason to believe that the manufacturers made every endeavour not only to make their preparations from active concentrates, but also to put them up in a stable form.

It is evident from the results obtained that the problem of preparing on a commercial scale stable concentrates of vitamins A and C has not yet been fully solved, at any rate in the case of preparations put up in the form of foods.

On this and on other grounds there would appear to be a prima facie case for including vitamin concentrates within the scope of the Therapeutic Substances Act, but there are certain difficulties in recommending this at present. The biological tests for vitamins are expensive and laborious, and their accuracy depends on meticulous attention to fine detail. They yield satisfactory evidence regarding gross differences in vitamin content, but no general agreement regarding minor points in technique has yet been attained, and until such agreement is reached it will be difficult to establish these tests as legal quantitative criteria.

England and Wales

Presentation to Dr. Arnold Lyndon

On the occasion of his retirement from the post of chairman of the Panel Committee, which he has held for the past nineteen years, and from that of honorary secretary of the Surrey Branch of the British Medical Association, which he has held for the past eight years, Dr. Arnold Lyndon was presented at the annual meeting of the Surrey Branch, held at Croydon on July 1st, with a handsome silver rose bowl and a cheque subscribed for by his colleagues in the area. In asking the president of the Branch to make the presentation, Dr. Morton Mackenzie outlined the work that Dr. Lyndon had done for the profession during his long life of service, laying more particular emphasis on the side of his work connected with the B.M.A., and stressing particularly Dr. Lyndon's unfailing courtesy and suavity under all conditions. Dr. Bates, the vice-chairman of the Panel Committee, gave an account of the work done on this committee, and said how, in spite of continued ill-health, Dr. Lyndon continued to devote himself to his duties. Dr. Genge, the president, in a few happy words, then made the presentation. Dr. Lyndon, who was enthusiastically greeted, briefly returned his thanks.

Instruction in Tropical Medicine and Hygiene

An important announcement is made by the authorities of the London School of Hygiene and Tropical Medicine in regard to the future post-graduate courses of study in tropical medicine and hygiene. The five-months' course of intensive study hitherto in force, followed by examinations, first for the School certificate, and then for the diploma of the Conjoint Board of the Royal Colleges of Physicians and Surgeons, has been found to impose an undue strain upon candidates. In addition, many of the Colonial Governments have found it difficult to release their officers for a sufficiently long period to enable them to combine what is in effect six months' study leave with a much-needed holiday in this country. Further, the requirements of the Colonial Service have been repeatedly of so urgent a character that for recruits about to proceed over-seas there has been a demand for a shorter course of instruction than has hitherto been possible. The whole situation has now been reviewed, and, after consultation with the Colonial Office and the Conjoint Board, the School authorities have divided the course of study into two parts: Section A, a three-months' course of clinical and laboratory instruction, and Section B, a two-months' course in tropical hygiene. Each section has been so designed that it can be taken independently of the other, and the Conjoint Board is arranging for the dates of the examinations to follow closely upon the end of the corresponding course of study. The examinations for the School certificate will be discontinued, and students will be encouraged to sit for the D.T.M. and H.Eng. Application has been made to the University of London for recognition of the revised course of study as a recognized course for associate students, and every student at the School, whether sitting for the diploma examination or not, will be entitled to apply to the University for a certificate of attendance at the recognized course of study. The dates of the courses for the session 1931–32 are:

Section A (Clinical and laboratory instruction).—First course: September 29th to December 18th, 1931. Second course: January 4th to March 24th, 1932. Third course: April 11th to June 30th, 1932.

Section B (Tropical hygiene).—First course: January 18th to March 18th, 1932. Second course: April 18th to June 17th, 1932.

The course of instruction under Section A includes clinical tropical medicine, applied pathology, medical zoology, and elementary bacteriology. Section B comprises instruction in tropical hygiene, including bacteriology, medical zoology, anthropology, and vital and medical statistics. An interesting development in connexion with the revised course is the establishment within the London School of Hygiene and Tropical Medicine of a new division of clinical and tropical medicine, with Dr. G. Carmichael Low as director and Dr. P. Manson-Bahr deputy director. The instruction in this subject will be given in the new division by the medical staff of the Hospital for Tropical Diseases and by visiting lecturers. In this way the splendid resources of the hospitals of the Seamen's Hospital Society at Endsleigh Gardens, at the Albert Docks, and elsewhere become available for clinical instruction of the students at the School. It is also announced that the course for the University of London D.P.H. has been revised so that the period of study is now covered by nine months' whole-time work. A further development is the establishment in the School of a university chair of medical industrial psychology, with Professor Millais Culpin as its first occupant. The course for the D.T.M. and H., the revised course for the D.P.H., and the course for the diploma in bacteriology and other special courses all commence at the end of September or the beginning of October. Inquiries should be addressed to the secretary of the School at Keppel Street, Gower Street, W.C.1.

Midwives' Institute Jubilee

The Incorporated Midwives' Institute celebrated its jubilee on July 4th by a meeting at Bedford College, London, at which the proceeds of a jubilee fund, amounting to £1,889, were presented to Miss Rosalind Paget, the treasurer and one of the founders of the Institute, to be used as a nucleus for the provision of a new home for the work, which has outgrown its present premises at Buckingham Street, Strand. A message was read from H.M. The Queen:

"I congratulate the members on their fine record of achievement, which owes much to the life-long devotion of the senior member (Miss Paget), under whose inspiration, I trust, this noble cause will meet with increasing prosperity. The great value to the community of the daily work of midwives is inestimable."

The Marchioness of Salisbury, in presenting the fund to Miss Paget, together with a book in which were inscribed the names of the pioneers and founders, said that the Institute during the last fifty years had accomplished much for the improvement of maternity services and for the increased welfare and status of midwives. In the early days everywhere midwifery was in the hands of women, though in England, curiously, it was under the control of the ecclesiastical courts; the first licence was granted by Bishop Bonner in 1554. As time went on and medical men began to take up midwifery practice, the midwife's status deteriorated. The last bishop's licence was issued in 1786. Attempts were made from time to time thereafter to awaken the national conscience on the subject, but very little was achieved, until, in 1880, a small body of ladies decided in a quiet way to improve the service and to set about obtaining State recognition and proper training for midwives. In the year (1881) that the Midwives' Institute, then called the Matron's Aid Society, was founded, it was stated that at least seven out of ten births were attended by women, most of whom had no training or qualifications. The Midwives Act, finally passed in 1902, was preceded by the introduction of ten unsuccessful Bills over a space of twelve years. Then came the work of training a great number of midwives, and in due time the fight to have the midwife included with the doctor in the provisions of the National Health Insurance Act. Mr. R. C. Elmslie presented a gift on behalf of the Chartered Society of Massage and Medical Gymnastics, and other gifts were offered in memory of individuals.

Miss Rosalind Paget, who was described by Miss Edith Pye, the president of the Institute, as "the Florence Nightingale of Midwifery," gave an address of reminiscence. She spoke first, and gratefully, of the work of the Obstetrical Society of London, which instituted an examination for midwives in 1872, and, by the time the Central Midwives Board commenced the State examination in 1904, had certified over 10,000 women. The society was at one time threatened by the General Medical Council that if it continued this procedure its members would render themselves liable to a charge of infamous conduct in a professional respect. A compromise, however, was reached, the principal element of which was the abandonment of the beautiful large diploma and the substitution of a quite small certificate. Miss Paget paid a special tribute to three members of that society—namely, Dr. Grailly Hewitt, Dr. Charles Cullingworth (the first representative on the Central Midwives Board), and Sir Francis Champneys. A good deal of objection

Attention is drawn to the objectionable practice of depositing refuse in cellars, vacant houses, and other odd corners. During the year 3,764 accumulations of garbage and filth had been removed by the cleansing department after warnings had been given to the occupiers concerned. During the year 1,360 cases of overcrowding were recorded; of these overcrowded houses 866 were of one apartment and 474 of two apartments. It is pointed out that hitherto overcrowding has been determined on a cubic space standard—namely, an allowance of 400 cubic feet per person, irrespective of age. As the result of a survey of 1,395 houses, with a population of 6,051, it was found that only 59 of the houses were overcrowded according to the cubic space standard, while no proper sex separation existed in 275 houses; in 417 houses there were more than two persons per room. Lodgers were kept in 98 cases, and subtenants in 96, thus greatly influencing the extent of the congestion. With regard to smoke abatement, it is pointed out that this is one of the most serious problems now confronting sanitarians. The report states that in its efforts to reduce the smoke of Edinburgh to a minimum, the public health department has been well supported by industrialists and owners of public buildings, who have readily given effect to suggestions made.

Correspondence

MORTALITY FROM TUBERCULOSIS

SIR,—The above phrase forms the heading of an interesting article in the *Journal* of June 27th (p. 1127). Unfortunately the word "mortality" has acquired no exact scientific meaning. Sometimes it is used as the equivalent of the term "death rate," at other times it is used as the equivalent of "case mortality." Each of these terms, "death rate" and "case mortality," has an exact connotation; the word "mortality" by itself has not. The following are examples of the confusion arising from the use of this vague word "mortality."

1. Osler's *Principles and Practice of Medicine*, McCrae (tenth edition, p. 71), referring to scarlet fever, reads: "In Boston from 1894 to 1903 the ratio of cases per 10,000 ranged from 45.80 to 16.18, and the mortality from 3.94 to 0.60." Could anyone from reading this be sure whether the last two figures had reference to 10,000 of the population, or to 100 of the cases?

2. Last year a candidate for the D.P.H. was asked in an oral examination, "What is the mortality from tuberculosis?" He thought "case mortality" was meant, and he had no answer ready. The examiner probably meant "death rate"; and, if he had said so, the candidate could have answered him.—I am, etc.,

Belfast, June 30th. JOHN R. GILLESPIE.

HOG'S STOMACH IN PERNICIOUS ANAEMIA

SIR,—From time to time I have noticed references in medical literature to the failure of certain cases of pernicious anaemia to respond to treatment with preparations of hog's stomach. There are apparently three main reasons for this:

1. The preparation may be inactive. It is extremely important that an active preparation of hog's stomach should be used. During the last two years I have examined some twelve different preparations offered for sale in this country, and I propose to publish particulars of the results obtained at a future date. The products were administered to patients suffering from pernicious anaemia in the wards of the Manchester Royal Infirmary. The value of each preparation in the treatment of pernicious anaemia was assessed from its influence on the reticulocyte response and also the alteration (if any) observed in the blood counts. In brief, the results showed that only four of these preparations examined were active and suitable for the satisfactory treatment of cases of pernicious anaemia. It is necessary to bear in mind the fact that the price of any of these preparations is not a criterion of the activity. The cost varies from 8s. 6d. to 48s. per pound. Three of the four active preparations may be obtained at a reasonable cost to the patient. The majority of the more expensive preparations of hog's stomach are unsuitable and inactive; it is therefore important that when hog's stomach is prescribed an active preparation should be used.

2. The treatment may be inadequate. However active the preparation may be it is essential that at least one ounce by weight should be given daily until the blood count has returned to normal, when the dose may be reduced.

3. The condition may be aplastic rather than Addisonian anaemia.—I am, etc.,

JOHN F. WILKINSON,
July 4th. Director, Laboratory of Clinical Investigations and Research, Manchester Royal Infirmary.

MICROCEPHALY

SIR,—The answer to Dr. Noel Burke's further query is in the affirmative. Long before mental deficiency was ever heard of, craniologists in many parts of the world had divided crania, according to their size, into microcephalic, mesocephalic, and macro- or mega-cephalic, and they have done so because, as Quain's *Anatomy* states, "the capacity of the cranium affords the most convenient indication of the development of the brain." The same applies to the living head, though the methods of determination necessarily differ for the quick and the dead. These distinctions cannot be detected in their finer gradations by the naked eye, but require instruments of precision. It is, then, not I who use a "type name with a new meaning," but rather that "majority of students" who may possibly have overlooked some of these craniological distinctions. My own experience, for whatever it may be worth, has convinced me that if we graft on to existing clinical methods some of these anthropometric facts, together with even more recent discoveries in the ancillary sciences of embryology, neuropathology, and statistical science, the study of mental deficiency becomes intensely fascinating and, I think, more hopeful.

"Type names" in mental deficiency, like many other historical landmarks in medicine, have played their part and done it well, but the day is not now far distant when they will necessarily have to be replaced by newer and truer ideas.—I am, etc.,

Stoke Park Colony, Stapleton, Bristol, July 6th. RICHARD J. A. BERRY.

THE CEREBRO-SPINAL FLUID

SIR,—The article on a cerebro-spinal fever outbreak in the Royal Air Force by Whittingham, Kilpatrick, and Griffiths, which appeared in the *Journal* of June 27th, has interested me, but on page 1103 there is a statement with which I cannot find anyone to agree:

"Cases of meningismus had clear, sterile cerebro-spinal fluid, with a low cell count (about 10 cells per c.mm.) and a practically normal albumin content (0.03 to 0.05 per cent.)."

It is surely recognized that the protein consists of albumin (fine molecules), 0.02 per cent.; pseudoglobulin (medium molecules), 0.003 per cent.; and euglobulin (large molecules), 0.0005 per cent. Beyond 0.025 per

cent. there is a definite abnormal protein content of the cerebro-spinal fluid. The Maudsley Hospital (London University) holds perhaps the widest limits of interpretation, and its figures are 0.01 to 0.025 per cent., whereas some authorities *hold that normal can* be definitely shown to be constantly 0.02 per cent. precisely.

In view of the statement made that 0.03 to 0.05 per cent. is practically normal, it would be interesting to know what other factors were ascertained in these cases—as, for example, the Lange curve—remembering that in disease not only is the amount of protein increased, but the proportion of albumin to globulin may be greatly decreased. Thus in tabes and meningitis, with an increase of total protein, the proportion of albumin to globulin may become 3–4 of albumin to 1 of globulin (normal 7 to 1), while in general paralysis of the insane the proportion is 1–2 to 1, and the euglobulin may show as much as a thirtyfold increase. The Lange colloidal gold reaction, being probably associated with this globulin increase, becomes more intense as the globulin proportion increases; it is this increase in the large molecules which causes the precipitate in the Lange test (euglobulin comes down).

It would also be of interest to know the chloride content (normal 0.75 to 0.73), which is reduced from 0.7 to 0.6 in meningitis, and also the sugar content (normal 0.05 to 0.09), which is reduced from 0.02 to *nil* in cerebro-spinal meningitis. Again, the pressure was not stated—for example, as recorded with Greenfield's cerebro-spinal fluid manometer (probably the most reliable)—and the number of drops which came out per second (reckoning normal as one drop per second); also the colour of the cerebro-spinal fluid. Seeing that above 6 cells per c.mm. (and 1 to 5 is normal) is always considered abnormal, I take it that "low cell count" should read "relatively low cell count for this condition."

I feel sure that this further information in these cases would be *most instructive*.—I am, etc.,

L.C.C. Mental Hospital, Colney Hatch, June 27th. ALEXANDER CANNON.

TREATMENT OF DYSMENORRHOEA

SIR,—I should like to endorse what Dr. Curtis Webb says about the treatment of dysmenorrhoea by electrotherapy in your issue of June 20th. Diathermy applied, as he suggests, from front to back through the pelvis is of undoubted benefit. When the hymen is supplanted I prefer a metal vaginal electrode and a metal belt round the waist, but what I find most successful is a course of static wave treatment. A tube-shaped metal electrode is inserted into the rectum. The static wave acts as a general tonic to the pelvic organs, exciting cellular massage and phagocytosis, relieving congestion and stasis. At the same time it has a markedly beneficial effect in certain forms of constipation.

Static wave current is contraindicated if sepsis of the genital tract is present. In such a case surgical treatment might be indicated, but in cervicitis and endocervicitis intrauterine zinc or copper ionization (15 to 20 ma. for fifteen or twenty minutes twice a week), as taught by my father, the late Dr. Samuel Sloan, followed by diathermy, seems preferable to dilatation and curettage, the results of which are often disappointing.

The combination of endocrinology with electrotherapy has given permanent relief to many women afraid of operation who, before these methods were adopted, would have been condemned to suffering and disability, year after year, for one or two days every month.—I am, etc.,

London, W.1, July 1st. ELIZABETH SLOAN CHESSER, M.D.

M. P. Crowe, P. A. Fox, A. Sloan.

SIR,—In reply to Dr. Kennedy Hister, J. O'Donnell, request for figures to substantiate my for vacant regard to the treatment of dysmenorrhoea Royal College of I should like to point out that I can hardly pharma- letter, commenting on some statements by Mr. Wilson. Dunn, a medium for publishing the results of cases during nineteen years of practice. Nor could I, in the time available, produce such statistics. I have, however, made a rapid survey of my notes on 100 cases of dysmenorrhoea in women between the ages of 18 and 32 treated by exercise. Of these, 48 were severe cases, 43 of whom subsequently had painless periods, and 5 were relieved. Of the 52 milder cases, 49 became free from all disability and 3 were relieved. In scanning these notes I found that I had, during the same period of time, seven cases of failure. Five had slight pains only, and would not attempt the exercise. Two with severe dysmenorrhoea tried them once, but felt no better and did not continue. One of these, however, got much relief from hot baths.

I will not occupy further space with details, but I must explain that, as stated in published papers, I use the term dysmenorrhoea to include "*suffering of any kind* associated with the menstrual period," whether it be intense pain or merely a form of malaise. With this interpretation of the word dysmenorrhoea I presume that most women with a medium-sized general practice would see, at the least, twenty-five such cases during the year, and accumulate 100 cases in a few years. Naturally, only the severer cases find their way to the gynaecologists.

May I add, in reply to private correspondents, that I find exercises involving bending, swaying, and crouching movements the most efficacious, but they must be continued until a feeling of warm glow is produced, and, in obstinate cases, they may have to be repeated two or three times on the first day of the period for a few months.—I am, etc.,

Cheltenham, July 6th. ALICE E. SANDERSON CLOW.

TOXICITY AND FATAL DOSE OF TURPENTINE

SIR,—In Taylor's *Principles and Practice of Medical Jurisprudence* (eighth edition, 1928, vol. ii, p. 839) I find the following:

Toxicity and Fatal Dose.—Turpentine cannot be said to be very toxic. It may irritate the stomach as a primary effect, and after absorption it has a specific influence on the kidneys, causing irritation which may lead to inflammation. We are unable to find a recorded case of fatal poisoning by turpentine in an adult, so that the fatal dose must remain with the records (infra) in children.

On April 3rd, 1931, an adult male, aged 39, drank six ounces of spirits of turpentine, and after doing so collapsed and died. He was an alcoholic, and was recovering from a drinking bout. On making a post-mortem dissection over four ounces of turpentine were found in his stomach. This fluid was as clear as when he drank it. The lining of the stomach was completely macerated, and lying in small pieces in the gastric cavity. The wall of the stomach felt like leather, due to the action of the turpentine.

In view of the above statement in Taylor's *Medical Jurisprudence*, and not having heard of, or come across, a fatal case of turpentine poisoning in an adult, I am recording this case as one of interest, for there is no doubt that the direct cause of this man's death was the turpentine he drank.—I am, etc.,

Bulawayo, June 2nd. FRANCIS P. MAITLAND, Senior Government Medical Officer, Southern Rhodesia.

st interesting, as a good many public health authorities diagnose and quarantine for diphtheria on the morphological appearance of the suspected Klebs-Loeffler bacilli, after a short period of incubation on Loeffler's medium. The following facts, although well known to bacteriologists, have not yet permeated to the textbooks in general use.

During the year 1918 the Canadian hospitals in England were startled by the news that 50 per cent. of the wounds of returning soldiers were infected with diphtheria bacilli. The matter appeared to be a very serious charge, as the examinations in Canada had been carried out by experienced bacteriologists. The problem was immediately investigated, and after thousands of cultures had been taken the pathologists of the Granville Canadian special hospital in Buxton, Derbyshire, Drs. Janes, Thomas, and myself came to the conclusion that from an academic standpoint it was practically impossible to diagnose Klebs-Loeffler bacilli without testing for toxins in cultures by injection into guinea-pigs. We found strains that answered all the known tests on the various sugars, but in the end failed to produce toxins. The solution of our problem in those war days was greatly handicapped by the poor and uncertain quality of the sugars available.

Our conclusions were that no matter what morphological resemblances or sugar reactions a culture produced, it could not be called a culture of Klebs-Loeffler bacilli unless it produced definite and fatal toxins for the guinea-pig. Full particulars are available in the War Office Reports.—I am, etc.,

KEITH M. B. SIMON, M.B.,

-au-Prince, Haiti, June 9th. D P H Lond.

SIR,—I can record a case of catheter life even longer than that of Dr Judson Bury's patient. The man was a parson who died when he was 74, after having passed a catheter daily for fifty-four years. The history he gave was that while an undergraduate at Cambridge he was seized with what was probably transverse myelitis after very strenuous rowing His legs were completely paralysed and he lost control of the sphincters. His legs so far recovered that he was able to walk with a shuffling gait with the help of two sticks. But in all his long life he never afterwards once passed urine naturally. He used a lubricant for his catheter now and then ; sometimes he passed it without any, and sometimes he spat on it. He had had orchitis and cystitis many times, but told me that the passage was now so hard that nothing troubled him. I saw him only when he was an old man , he died of cancer of the rectum.—I am, etc.,

Yattendon, Berks, July 4th. F. A. BRODRIBB.

The Services

COMMISSIONS IN THE R A M C.

Twenty-five permanent commissions in the Royal Army Medical Corps are being offered to qualified practitioners, under 28 years of age, registered under the Medical Acts There will be no entrance examination, but candidates will be required to present themselves in London for interview and medical examination. At the same time, a certain number of temporary commissions, under similar conditions as regards age and qualifications, will also be offered. Applications should reach the War Office not later than July 20th. All information as to conditions of service and emoluments may be obtained from the Under-Secretary of State, War Office (A M D 1), Whitehall, S W.1.

Universities and Colleges

UNIVERSITY OF LONDON

At a meeting of the University Court, held on July 1st, Lord Macmillan presiding, intimation was received that the late Mr. J. F. H. Knight had bequeathed to the University a moiety of his residuary estate after the determination of certain trusts and the payment of certain legacies The bequest, which is for the furtherance of teaching and research in the University, was accepted. Its value is expected to be in the neighbourhood of £25,000.

The Semon Lecture, entitled " The relative value of radiotherapy in the treatment of cancer of the upper air passages," will be given by Mr. Douglas Harmer at the House of the Royal Society of Medicine on Thursday, November 5th, at 5 p.m

Dr. Kenneth Eckenstein, Deputy Esquire Bedell since 1920, has been appointed Esquire Bedell in succession to Dr. H. E. Vincent, resigned.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following have successfully passed the school examination at the termination of the nineteth term (February-July):

*H W. H McClelland (winner of " Duncan " Medal), *W A. Burnett, *C H Howat, *J A. Rosset, *E C Vardy, E S Adderley, E E Barnett, R V. Bowles, R N Brandwood, C J H Brink, R. Caldera, H. P. Chaudhuri, H. D Cronyn, B R Das, K. Edmundson, A. J. Johnson, F B. Khambatta, T. Langan, S. H. Moore, E. Morris, R Nicklin, P. J O'Shaughnessy, A Papadakis, N. C R. M Perumal, P. B Lee Potter, J L Razdan, O Rosset, V. Sivalingam, M H Steven, M M Siddiq, J. Taylor, R W. van Cuilenburg, F. A. Vlapree, L. A F. Wiles, A. W. Williams.

* Passed with distinction.

UNIVERSITY OF LIVERPOOL

A degree ceremony took place in St. George's Hall on Saturday, July 4th.

The following candidates have been approved at the examinations indicated.

M D—S Alstead, R. E. Horsfall, E. D. Irvine, J. Lobman, C L G. Pratt

M B, Ch B—[1] T. L Hughes, [2] W. J. Chisnall, [2] A L Potter *Part III (1923 Regulations)* : M L. Kaufman. *Part B (1924 Regulations)* : H. T. Cank, L M. Crooks, W S Diggle, H. G. Evans [illegible] H Hughes, O. V. Ice[illegible], W W. Laughland, J T. Lennon, H. F. Loewenthal, A J Martinez, P. B Moroney, I. Sytner, J V Tollington, Winifred Walls, A R Williams, D. I. A. Williams, A Wynroe. *Part A (1924 Regulations)* [3]H. Ackers, [3]D G. W. Brown, [3]W. Bullock, Mervyn H Clark, H. L Davies, [3]W. S Davies, [3]J. R. Eatough, [3]T R Edwards, J. F. Foulkes, [3]G. R Griffith, H G. Hanley, A J Helfet, F. P. J. Higgins, D J. Hoskinson, [3]E R Jones, [3]A S Kerr, Nancy L. Lewis, Margaret Mewton, [3]M H Papperovitch, I Parry, R. G. Reid, T. G. Richards, Beatrice L H Sergeant, A L Smallwood, [3]Edna L Smart, K. W. Stronde, D Wainwright, V. J. Woodward, R. F. Wynroe Passed in separate subjects J. Amos (special pathology, pharmacology, and general therapeutics), H V. Corbett (forensic medicine and toxicology, pharmacology, and general therapeutics), G R Critten (forensic medicine and toxicology), Eva Macdonald (public health), E Taylor (public health), G. E Thomas (special pathology, pharmacology, and general therapeutics), J. L Williams (public health)

D P H—*Part I* : Enid M. Hughes, D. H. Williams, Mary G T. Williams. *Part II* : A C Briffa.

DIPLOMA IN TROPICAL MEDICINE—J. A. K. FitzGerald

DIPLOMA IN TROPICAL HYGIENE—F. E Camps, E. R. Gauld, K. T. Moir, M Salah el Din, G. Verghese.

[1] First-class honours.
[2] Second-class honours.
[3] Distinction in surgery, obstetrics, and gynaecology.
[4] Distinction in forensic medicine.
[5] Distinction in public health
[6] Distinction in pharmacology and general therapeutics
[7] Distinction in obstetrics and gynaecology

The following fellowships, scholarships, and prizes have been awarded in the Faculty of Medicine

Lady Jones Research Fellowship in Orthopaedic Surgery Dr E. N Wardle. *John Rankin Fellowship in Anatomy* Dr G W Causey. *Johnston Colonial Fellowship in Biochemistry* Dr R W Brookfield. *John W Garrett International Fellowship in Bacteriology* : Dr Honora J. Twomey. *Holt Fellowship in Pathology* : Dr D. H Collins *Holt Fellowship in Physiology* Dr C I G Pratt. *Thelwall Thomas Fellowship in Surgical Pathology* Dr R. A Furniss *Robert Gee Fellowship in Human Anatomy* Lennon *Samuels Memorial Scholarship (Medicine)* Dr C A Birch *Samuels Memorial Scholarship (Surgery)* Dr M Silverstone *University Graduate Scholarship in Medicine* A S Kerr *John Rankin Exhibition in Practical Anatomy* : Divided between Margaret F. Procter and M. M. Wallis. *Owen T. Williams Prize*:

T. L. Hughes. *George Adami Prize in Pathology:* A. S. Kerr. *Thomas H. Bickerton Prize in Anatomy:* B. Bland. *Torr Gold Medal:* Margaret F. Procter. *William Mitchell Banks Bronze Medal:* A. C. Brewer. *Gold Medal in Public Health:* E. R. Jones; *proxime accessit,* A. S. Kerr. *Silver Medal in Pharmacology:* S. Henderson. *Silver Medal in Forensic Medicine and Toxicology:* A. S. Kerr; *proxime accesserunt,* W. S. Davies and J. R. Eatough. *Kanthack Medal:* A. S. Kerr.

UNIVERSITY OF BIRMINGHAM

At a congregation of the University of Birmingham, held on July 4th, the following degrees were conferred:

M.D.—A. C. R. Walton (with honours), G. H. Knight, H. J. Williams.

M.Ch.—J. Gore.

M.B., Ch.B.—*†H. N. Gregg, *A. G. W. Whitfield, F. H. C. Boards, J. A. R. P. Cant, W. S. Coltart, H. L. N. Davies, R. J. de Carteret, T. A. S. Kennerley, Nancy Laughton, H. J. Riley, E. Rudkin, M. H. Sherwell, R. B. Fitz-A. Usher-Somers.

The following scholarships and prizes have been awarded:

Queen's Scholarships: (Third year) R. M. Case, (fourth year) C. S. Whitehouse, (fifth year) A. H. Barber, (final year) H. N. Gregg. *Ingleby Scholarship:* (Final year) H. N. Gregg. *Arthur Foxwell Memorial Medal:* (Final year) H. N. Gregg. *Sampson Gamgee Memorial Medal for Surgery:* (Final year) A. G. W. Whitfield. *Priestley Smith Prize for Ophthalmology:* (Final year) A. G. W. Whitfield. *Russell Memorial Prize:* R. W. C. Murray. *Peter Thompson Prize in Anatomy:* (Third year) Phyllis M. Ball.

* With second-class honours. † Distinction in medicine and in midwifery and diseases of women.

UNIVERSITY OF DURHAM

At a convocation held on June 30th, the honorary D.C.L. degree was conferred upon Dr. Robert Muir, F.R.S., professor of pathology in the University of Glasgow.

The following medical degrees were conferred on July 1st:

M.D.—G. McCoull, T. S. Severs.

VICTORIA UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

Ch.M.—A. A. Davis.

First M.B., Ch.B.—*§¶T. S. Heslop, †‡‖¶Nancy N. Carter, †J. C. Smith, †§G. G. E. Smyth, F. Cort, H. B. Craigie, P. M. Crowe, F. Livesey, Edith A. Longson, ¶J. P. Longworth, S. Mills, G. Ramage, J. Scully, B. Stone, I. Sutton, K. Todd, C. H. T. Wade. (*Part I—Forensic Medicine and Hygiene and Preventive Medicine*): Nancy Anderson, S. S. Andrew, F. Bagot, A. S. Beer, Kathleen M. Boves, M. M. Cohen, Patience Craig, A. W. Davies, B. Finkleman, B. Gold, C. H. Gray, D. L. Griffiths, C. C. Hurst, M. C. G. Israels, J. D. Lendrum, W. A. B. Nicholson, *H. C. Palin,* J. S. Parkinson, C. E. B. Rickards, B. Sheehan, S. Sutton, R. Whittaker, D. J. Williams, R. V. Wright, P. Zimmerman.

* First-class honours. ‖ Distinction in surgery.
† Second-class honours. § Distinction in medicine.
‡ Distinction in obstetrics. ¶ Distinction in forensic medicine.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examination indicated:

M.D.—E. S. Clayton, J. N. Gale.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

ELECTION TO THE COUNCIL

On July 2nd three Fellows were elected into the Council to fill the vacancies caused by the retirement in rotation of Mr. J. Herbert Fisher, Mr. G. E. Gask, C.M.G., D.S.O., and Mr. Graham Simpson.

The result of the poll was as follows:

	Votes.		Plumpers.
GRAHAM SCOTT SYMPSON (Sheffield)	659	...	73
GEORGE ERNEST GASK (St. Bartholomew's)...	635	...	12
ALBERT JAMES WALTON (London Hospital) ..	544	...	35
Herbert Sherwell Clogg	360	...	16
John Herbert Fisher	351	...	18
Herbert John Paterson	297	...	12

In all, 1,105 Fellows voted, including 193 Fellows resident out of Great Britain and Ireland; in addition, one vote was found to be invalid, and six were received too late.

Mr. Simpson and Mr. Gask are re-elected, and Mr. Walton is elected for the full period of eight years.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the President and Fellows, held on July 3rd, the Licences in Medicine and Midwifery of the College were conferred on the following candidates, who had passed the Conjoint Final Examination held in June, 1931: T. J. Conlon, M. P. Crowe, P. A. Fox, J. L. Hampson, Mary G. A. M'Allister, J. O'Donnell, Y. Posner, J. V. Quinn, J. Rubinstein, G. A. Steen.

A letter was read from the registrar of the Royal College of Surgeons in Ireland, forwarding applications for vacant professorships in the Schools of Surgery, as follows: pharmacology, Dr. L. Abrahamson; midwifery, Dr. A. H. Davidson. These candidates were duly nominated for the respective chairs.

Nominations for the Fellowship were received, elections to take place on the morrow of St. Luke's Day, 1931.

The representative of the College on the General Medical Council reported on the recent proceedings of the Council.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Coal Mines Bill, regulating hours in mines for twelve months, was hurried through Parliament this week. The House of Commons also considered the Unemployment Insurance Bill and debated Indian administration. In the House of Lords, on July 7th, the Merchant Shipping (Safety and Load Line Convention) Bill was read the third time and passed. The Bethlem Hospital (Amendment) Bill passed the report stage. The Marriage (Prohibited Degrees of Relationship) Bill was read a second time. In the House of Commons, on July 7th, the financial resolution authorizing the Ministry of Health and the Scottish Department of Health to assist rural district councils in England and county councils in Scotland in providing houses was agreed to in committee.

Progress has been made in Standing Committee with the Slaughter of Animals Bill.

Major Church has given notice that, on July 21st, he will introduce a Sterilization Bill—"to enable mental defectives to undergo sterilizing operations or sterilizing treatment, upon their own application or that of their spouses or parents or guardians, and for purposes connected therewith."

Poisons and Pharmacy Bill

Replying to Mr. Bromley, on July 2nd, Mr. CLYNES said there had been misunderstanding about the scope and objects of the Poisons and Pharmacy Bill. The Bill was based upon the recommendations of a Departmental Committee which was appointed by the previous administration and reported in 1930. The committee, which, apart from its pharmaceutical members, was entirely independent of any of the commercial interests affected, found that the existing position relating to poisons was far from satisfactory, and the object of the present Bill was to provide for a wider and much more effective regulation of poisons than existed at present. He understood that the pharmaceutical associations took exception to the Bill on two main grounds. First, they demanded that all doctors' prescriptions, whether they contained poisons or not, should be dispensed by registered pharmacists only. This proposal did not come within the scope of the Bill, and it had never been investigated, and even if it were, and there was found to be a case for considering that the demand was in the public interest, the Government could not ask Parliament to adopt such a proposal except after adequate inquiry, and after the persons who would be affected by the prohibition had had an opportunity of stating their case. Secondly, the pharmacists demanded that the increased facilities which the Bill proposed for the supply to farmers of agricultural poisons should be limited to firms carrying on a bona fide business in the supply of agricultural requisites. He was advised by the Ministry of Agriculture and by the Board of Agriculture for Scotland that this limitation would not make adequate provision for legitimate needs in the more rural districts. The Government, however, had decided to propose an amendment to the Bill, which would have the effect of requiring the Poisons Board and the Secretary of State, in considering the allocation of poisons as between Part I and Part II, to have regard to the desirability of restricting the contents of Part II (which would contain the list of poisons which might be sold

by persons other than pharmaceutical chemists) so far as was consistent with the provision of adequate facilities for the public to obtain supplies of non medical substances which were in common use Mr Clynes told Sir Kingsley Wood that the Government wished to get ahead with the Bill and to pass it into law, with the amendments to which he had referred

Sickness Benefit

Replying to the Marquess of Titchfield, on July 2nd, Mr GREENWOOD said he was aware of a statement to the effect that out of a large and representative group of insured persons who were in receipt of sickness or disablement benefit on a certain day, and whose title to benefit was made the subject of special investigation, it was found that 12 per cent were capable of work and consequently not entitled to benefit He had already addressed circulars to all insurance medical practitioners and approved societies on the steps to be taken to avoid payment of benefit to persons not entitled.

London Post-Graduate School

Miss LAWRENCE, on July 6th, replying to Mr Hastings, said that a Royal Charter constituting the governing body of the British Post-Graduate Medical School and defining the functions of the governors, was approved by the King in Council on June 29th Active steps were being taken in collaboration with the London County Council to proceed as quickly as possible with the planning and building of the school, and with the adaptation of the Hammersmith Hospital for the purposes of post graduate medical education Mr HASTINGS asked if Miss Lawrence had any idea when the school would be opened for teaching purposes Miss LAWRENCE said that she could not say at the present moment

Vaccination and Encephalitis

On July 7th Mr FREEMAN asked the Minister of Health the result of his inquiries into the death of the twin children of Councillor A A Furness of Wigston, near Leicester, following vaccination Miss LAWRENCE said that inquiries which were made locally by a medical officer of her department during the life of one of the children, taken with the evidence now available from pathological examination of material from in each case, showed that these deaths obtained post mortem were both caused by post vaccinal encephalitis, and were comparable to those cases which had been fully studied and described in the recent reports of the Committee on Vaccination The Minister of Health did not consider that a public inquiry could advance our knowledge of the circumstances in which this rare complication of vaccination developed, or that any useful purpose would be served by such an inquiry Mr FREEMAN asked whether, "in view of the fact that vaccination was now discredited by a large majority of the population" an inquiry into such cases as this would not afford an opportunity to the Government to justify the repeal of the compulsory clauses on vaccination Miss LAWRENCE said that Mr Freeman was merely repeating his question which she had answered Sir K WOOD asked if Miss Lawrence proposed to make any statement in reply to Mr Freeman's allegation in regard to vaccination Sir F HALL asked if the Government subscribed to Mr Freeman's statement Miss LAWRENCE replied that she did not think the question arose

Telephone Concessions for Midwives

On July 6th the Countess of IVEAGH asked the Postmaster General if he would consider special telephone facilities to midwives in view of the fact that many of them were unable to afford the telephone at trade rates, and that a certain number of maternal deaths were due to failure to secure prompt attention Mr ATTLEE replied that the residential rate already applied in any case where nursing was not carried on at the house, and where the entry in the telephone directory made no explicit reference to the subscriber's profession He regretted that he was unable to make any further concession Lady IVEAGH asked whether Mr Attlee would consider the special position of the country midwives Mr ATTLEE said that he recognized that the question was important but there were other applications of a similar sort, and it was extremely difficult to draw a line. The question of assisting midwives in this matter was more for the local authority concerned with health services than for the Post Office

Tuberculosis in the Navy—Replying to Sir N Grattan Doyle, on June 24th, Mr ALEXANDER said the incidence of tuberculosis among naval ratings serving with vessels at sea was approximately 3 per 1,000 In spite of careful investigation no definite reason had been ascertained to account for the relatively high incidence of pulmonary tuberculosis in the *Warspite* during 1929 It could only be assumed that it was due to fortuitous circumstances, as in 1930 only one case occurred in this ship

Branding of Tuberculous Cattle—Mr GREENWOOD told Mr Blindell, on June 25th, that a suggestion that all animals tuberculin-tested for the purpose of the Milk (Special Designation) Order of 1923, and which reacted to that test should be branded before sale had been considered and held to be undesirable It would be inexpedient to make any such requirement regarding the limited number of animals in herds to which the Special Designation Order applied If this test were applied to all cattle there would be enormous slaughter Mr SANDHAM suggested, in a supplementary question that at least 40 per cent of cattle producing milk in the United Kingdom would be affected

Refuse Dumps—Mr GREENWOOD, in reply to Mr Muggeridge on June 25th, said by-laws regarding dumping of house and trade refuse in their areas had been made by Barking Urban District Council and Orsett Rural District Council, though those of the latter had not yet been confirmed by his department Other authorities in Essex were preparing by laws Large quantities of refuse were still being dumped in South Hornchurch He was not yet able to say when legislation on the subject would be introduced

Millman Street Hospital, Chelsea—Mr GREENWOOD told Dr Morgan, on June 25th, that the figure of 56 days as an average duration for patients in a London clearing tuberculosis hospital [Millman Street Hospital, Chelsea—see June 27th, p 1143] took account not only of patients received in this hospital for observation purposes, whose average stay was from four to five weeks but also of advanced cases, which might remain for much longer periods

Asbestosis—Mr SHORT told Mr Muggeridge, on July 1st, that he had received a report from a medical inspector concerning an inquest at Barking on a packer in an asbestos works Death was due to cancer, but asbestosis of the lung was also present Mr Short would consider the suggestion of amending the medical arrangement scheme under the Silicosis (Asbestosis) Acts, 1925 and 1930, to apply to packers but no danger had hitherto been apprehended from the packing of the manufactured materials

Civilians and Poison Gas—Mr RAMSAY MACDONALD told General Clifton Brown on July 2nd, that the scheme detailing measures which should be taken for the protection of civilians from poison gas had been brought before the Standing Subcommittee of the Committee of Imperial Defence concerned with these matters, and was receiving attention Foreign nations were known to be actively studying this question, but he was unable to say what steps they were taking The ratification of the Geneva Gas Protocol in 1925 by most of the countries in Europe provided an important safeguard against this form of attack General Clifton Brown could certainly have assurance that this matter of the protection of civilians was receiving attention

A Plague of Bugs in Westminster—Mr GREENWOOD told Sir Martin Conway, on July 2nd that he was not aware that, owing to the recent destruction of some slum houses in Westminster which belonged to the London County Council a plague of vermin notably of *Icanthia lectularia*, had invaded certain streets within the borough He had no power to give directions to disinfect the houses attacked, but he would communicate with the local authorities

Schools for Mentally Defective Children—Mr LEES SMITH told Mrs Manning on July 2nd, that the number of special schools for mentally defective children opened in 1926 was five, in 1927 four, in 1928 none, in 1929 four, and in 1930 one Mrs MANNING remarked that, of 105,000 mentally defective children in this country, only 16,000 were in special schools.

Obituary

EDWARD BEADON TURNER, F.R.C.S.

Member of Council and former Chairman of Representative Body, British Medical Association

As announced in our last issue, Mr. E. B. Turner, the oldest member of the Council of the Association, and a former Chairman of the Representative Body, died on June 30th in his London home, at the age of 76. Until recent months Mr. Turner had been a man of exceptional vigour, apparently immune from the infirmities of advancing years. A lifelong devotion to athletics perhaps accounted for his immense vitality. In a message apologizing for his absence from the last meeting but one of the Council, he mentioned that he had never missed a meeting of the Council for twenty years; he also told the last Annual Representative Meeting that he had attended every session since he first became a representative for the Kensington Division in 1912. He celebrated his seventy-fifth birthday by driving a motor car from Yorkshire to London at an average speed of thirty-five miles an hour, and declared that he felt absolutely untired at the end of the journey. An illness in the spring of this year wrought a tragic change, and when, with great fortitude, he attended for a short time the meeting of the Council on June 10th, his colleagues were shocked to observe the change in his appearance. In reply to a welcome by the Chairman, endorsed by affectionate applause, he rose and said, pathetically, that he felt he must come, if only to say good-bye.

Edward Beadon Turner was born in 1854 at Chigwell in Essex. His father was a London man, and London was the scene of Turner's interests and activities throughout his career. He received his schooling at Uppingham, where Edward Thring—next to Arnold perhaps the greatest schoolmaster of the nineteenth century—was then reigning. It was probably from Thring that young Turner imbibed his love for what he called the discipline of the classics. It was a love which showed itself, along with other attractive little mannerisms in his fluent and picturesque oratory, by a fancy for Latin tags. He rarely made a set speech on any important occasion without introducing, always with a little apology lest it should be thought a conceit, a quotation from some Latin poet.

From Uppingham he went to St. George's Hospital, qualifying in 1876, and taking the Fellowship of the Royal College of Surgeons of England in 1881. He then settled down in private practice in one of the most prosperous parts of London, bordering Hyde Park. He once described his practice as having been among the well fed, the well clothed, and the well housed, with the result that even in fifty years he saw astonishingly few cases of pulmonary tuberculosis and such maladies. He was a family practitioner *par excellence*, and not long ago he mentioned that he had two families in his practice in each of which he had attended five generations.

From his schooldays right to the end of his life his interest in sport and athletics was unabated. He was a well-known figure at important Rugby matches. His love of football dated from his Uppingham days, and he was president of the Old Uppinghamian Football Club. It was in the flurry of a football field in Dublin that, as a young man, he first came into contact—physical contact—with the late J. A. Macdonald, with whom in later years he was destined to be so closely associated in the work of the British Medical Association. E. B. Turner played in the English Rugby twenty in 1875 and (with his brother, Sir George Turner) in 1876, and in the English fifteen in the two following years. He was a vice-president of the London Athletic Club, and its president in 1913. He was also a vice-president of the National Cyclists Union, and in his time made many records with the pedal. Another proficiency of his was denoted by his extra-master's certificate in navigation. Down to his septuagenarian days he kept up many forms of sport, including yachting, cycling, and skating. When, in 1927, he addressed newly qualified practitioners and advanced students at the reception given by the Metropolitan Counties Branch, he urged them to take up sport as a hobby, more than one branch of sport if possible, and to play a strenuous game.

It was his love of sport which helped to make him in due time so splendid a figure in the British Medical Association. He brought into his work on behalf of the profession the same keen enjoyment and zest, the same abundant energy, and, above all things, the same capacity for working in a team, sharing the fortunes of a side, and throwing in his own individual contribution without stint as he had shown on the playing field. A strong individualist, an outspoken debater, he was nevertheless able to work admirably with others, to accept defeat gracefully, and to go on serving with undiminished loyalty. His own special experience and environment led him to take a stronger line on some matters than his colleagues. He believed intensely in private practice, disliked all movements towards the nationalization of medicine, and

never quite reconciled himself to national health insurance. But his invariable courtesy, as well as his evident sincerity, made him honoured by opponent and friend alike.

His active entrance upon the central affairs of the British Medical Association dated from 1912, when he became a member of the Council. He was chairman of the Kensington Division in 1913, became a member of the Metropolitan Counties Branch Council in 1914, and was president of the Branch in 1927–28. In 1915 he was unanimously elected chairman of the Representative Body, which position he held for three years. His power of command over assemblies was shown to its best advantage in that capacity. He never allowed red tape to strangle common sense. His period of office was during the war years, when the Representative Meeting was contracted to two days, and he confessed that he was rather a slave-driver, but said that when time allowed more leisure he would be found the most indulgent of chairmen.

His work for the Association is illustrated by the formidable list of committees and subcommittees of which he was at various times a member. To describe it adequately would mean writing the history of every considerable enterprise of the Association during the last fifteen years. During the whole of that time he was a member of the Medico Political Committee, and its chairman for seven fruitful years, during which he presented on its behalf to the Council and Representative Body a varied volume of work. During the war he was vice-chairman of the Central Medical War Committee under his friend Sir Jenner Verrall, whom he himself proposed for the chairmanship. He was accustomed to say that the work of that committee was the greatest achievement of the Association. He was a member of the old Ministry of Health Committee, the Science Committee, the Parliamentary Elections Committee, and the Ophthalmic Committee. Innumerable special committees commanded his services, such as those concerned with the expansion of the Army Medical Service in case of national emergency, the memorial to fallen members, the presentation of evidence to the Royal Commission on National Health Insurance, minimum salaries for public health appointments, the problem of puerperal mortality and morbidity, the amendment of the lunacy law, the elaboration of tests for drunkenness, the examination of motor drivers, the health of merchant seamen, and the training of ship surgeons. There was much else to which he set his ready hand—work designed to improve the position of asylum medical officers, prison medical officers, laboratory and research workers, Post Office medical officers, and medical officers of public schools. One wonders how a man even of the most various mind and abundant energy could contribute effectively, as he did, in so many directions.

The British Medical Association by no means exhausted his energies. He looked back with special pride upon his part in the campaign against venereal diseases. He was president of the Section which dealt with this subject at the Cambridge meeting in 1920, and his interest therein was both scientific and sociological. Twenty-five years earlier he had been one of the first to impress systematically the gravity of this subject upon the public. During and after the war he carried out a programme of public speaking which amounted to something like 2,000 meetings—an itinerary which would have made John Wesley envious—and his resonant voice reached perhaps a million men. The value of Turner's work in this respect was immeasurable, for he was a man who commended his gospel by his own vital hold of the best things of life. His was always the voice of conviction, and he never let down the ideal; but he was no remote preacher—he was full of human sympathy and understanding. Turner was a Puritan, but a laughing one, and gifted uncommonly with the grace of straightforward, persuasive utterance. His enthusiastic work for the National Council for Combating Venereal Disease (now the British Social Hygiene Council) is referred to in one of the appreciations printed below.

For the five years 1920–25 he served as a direct representative on the General Medical Council. For four years he was chairman of the Central Council for District Nursing, and once declared that his experience of nurses went back to the time when Sairey Gamp was scarcely cold in her grave. Among the local appointments which he had held were those of visiting apothecary at his old hospital (St. George's), physician to St. Mary's College, Lancaster Gate, consulting physician to the Princess Helena College, and inspector of special constabulary, of one division of which he was for a time chief medical officer. He was always busier with his voice than with his pen, and his writings are mostly in periodicals. In 1891 he contributed a paper on 200 cases of influenza treated with large doses of salicin. He also wrote a good deal on the fight against venereal diseases, and on the hygiene of sport.

Among those present at the funeral service on July 3rd were Mr. Bishop Harman, Mr. McAdam Eccles, and Dr. Christine Murrell, members of Council of the British Medical Association; Dr. F. W. Goodbody, Mr. Howard Stratford, and Dr. C. F. T. Scott of the Metropolitan Counties Branch Council; Dr. Alfred Cox, Medical Secretary; and Dr. David Roxburgh.

Mr. N. BISHOP HARMAN, Treasurer of the Association, writes:

E. B. Turner—for so everyone called him with an affectionate familiarity—was no ordinary man. His exceptional physique marked him as notable, and his forceful personality turned that to great advantage. It is small wonder that a man with such natural endowments should have achieved success and fame in many fields of endeavour. They accounted for his powers and his successes in athletics in his younger days. He loved any sport that called for personal fitness and strenuous exertion, and he was able to enjoy this to an age that brings to most a desire for ease. His love of the field was but one side of his character, for he loved his fellow man as heartily, not with any mawkish sentiment, but with a vigorous good fellowship that was as robust as his physical strength. He was intensely public-spirited. No call for service in connexion with any form of social activity which he deemed good failed to secure his aid. He was an enthusiastic worker for his old school, for his athletic associations, for his medical school, and not least for the British Medical Association. In the work of our Association he made a deep impression, both in Divisional affairs, in the Metropolitan Counties Branch Council, and in the work of the Central Council and Representative Body. Of his powers as a debater none could be in doubt who has attended a meeting of the Representative Body. Not for him any chopping of fine logic, but a forthright slashing frontal attack that was almost overwhelming in its force and weight. But I am inclined to think that of all his work during recent years, that most near to his heart was the share he took in propaganda for combating venereal disease. This work seemed to hold first place with him. He detested venereal disease with his whole soul, and he spent himself journeying from place to place lecturing to crowded audiences of men. He began this work during the war by speaking to recruits, and he continued it on a wider scale for years thereafter. As a platform orator few could match him. He had a way with him that was irresistible. His bluff, hearty speech, his manner of taking

, confidence, and his manifest sincerity an influence upon his hearers that was lasting. The finer side of his character his reaction to illness. An accident at udent days left him with a permanent he overcame it. The disability and suffering llness, the significance of which he knew only was borne, not merely uncomplainingly, but a spirit of light-hearted stoicism that was . A man has gone from among us, but his le remains.

R. CHRISTINE MURRELL writes:

Mr. E. B. Turner and I became acquainted in our work for the British Medical Association. First we served together on the local Executive Committee of the Kensington Division, later representing it on the Metropolitan Branch Council and also on the Central Council. Public spirit inspired all his work for the Association. He brought to the problems of the profession the breezy outlook of the good sportsman, and, while making allowances for the different views of his fellows, held his own opinions with tenacity; he was ever generous in his appreciation of the work of others, and gave his own time without stint.

At the time of the great war he deeply regretted that he was too old to be accepted for active service, but found outlet for his patriotism by serving throughout as medical officer with the F Division of the Special Constabulary. It was through his introduction that I also was enabled to serve in a similar capacity, Dr. Charles Buttar making a third. Whereas we were only called out on two occasions to deal with the casualties caused by enemy bombs, we had continuous medical duties in the care of the many hundreds of people who took shelter during the raids at the local police station. In this capacity we attended on over seventy occasions, often remaining on duty for many hours, and during these times we became friends as well as associates in work. Mr. Turner was the soul of energy, and would never admit fatigue; not only did he live the strenuous day of a doctor in general practice in war time, but also worked indefatigably for the Central Medical War Committee, and the sleepless nights of his special constable duty undoubtedly took their toll. Serving and waiting thus together, one became aware of the golden store of classical knowledge which he possessed, whence he minted the ready phrases and apt allusions so characteristic of him. Truly his was a richly furnished mind.

In looking back over many years of association with him in public service, the qualities of E. B. Turner which live in the memory are his courage, generosity in his attitude towards others, and devotion to the public weal; he leaves behind him the greatest gift which a man can give his fellows—an example. A fine sportsman and "a very gallant gentleman."

The MEDICAL SECRETARY writes:

The death of Mr. Turner removes not only the senior member of Council, a past Chairman of the Representative Body, and an active member of many committees, but also an outstanding personality who will be very greatly missed. I well remember his debut in central Association circles, in the stormy times when the national health insurance system was in the making. All of us recognized the advent of an ardent upholder of the traditions of the profession (which he believed the insurance system was likely to damage) and a speaker of uncommon quality. At first it looked as if he might be merely the stormy petrel, who, after the storm was over, would disappear, but we soon found that the Association had secured a man who was prepared to give his whole energies and talents to its service. His extensive knowledge of practice and of men and affairs was freely placed at our service, and this was speedily recognized by his election to all sorts of posts which carried with them both honour and hard work. He worthily upheld the traditions of the Chairmanship of the Representative Body, and the list of committees of which he was either chairman or a member, which is at the moment before me, is a vivid testimony to his activity and devotion.

Special mention should be made of his work as vice-chairman of the Central Medical War Committee from 1915 to 1919, entailing exceedingly strenuous and difficult duties, which he fulfilled with great credit to himself and to the committee. His activity in connexion with the British Social Hygiene Council, on which he acted for many years as representative of the Association, will no doubt be dealt with by others who have a more intimate acquaintance with it than I have, but it was work for which he was eminently suited, and he was seen at his best as a popular exponent of subjects which required exceedingly delicate handling, and which his record as an athlete and his all-round knowledge of sport peculiarly qualified him to deal with. He represented the Council on many other outside bodies, and was always a *persona grata*. The honorary secretary of the National Safety Week Council has just written me in words which will be endorsed by all who knew Mr. Turner: "His cheerful personality and happy outlook on life endeared him to all with whom he came in contact, and his presence will be sorely missed."

As might have been expected, he carried on to the very end. I had several letters from him during his illness, all of which showed his usual optimism and courage, though one knew he was suffering badly. Up to within a short time of the end he hoped to get back again to his work, for he was very anxious to carry on until the Centenary Meeting was over, after which, as he said, he thought he would have earned his retirement. It gives me a sad pleasure, as one who worked with him intimately for many years, to testify to his never-failing consideration and comradeship, and to end what I have to say on the note I am sure he would have liked—not of sadness, but of grateful appreciation of a man who put zest, gaiety of spirit, and courage into everything he did.

Mrs. C. NEVILLE ROLFE, Secretary-General of the British Social Hygiene Council, writes:

In Mr. E. B. Turner the country loses one of its most public-spirited and self-sacrificing servants. From 1921 until his death he was a vice-president of the National Council for Combating Venereal Diseases, which is now known as the British Social Hygiene Council. For over forty years he was connected with an organization formed for an official inquiry into the prevalence of venereal disease, which continued until the Royal Commission was appointed. It was soon after the formation of the N.C.C.V.D. (1914) that Mr. Turner, together with other members of his committee, joined the organization, on which he was appointed by the British Medical Association as its representative in 1915. From that date until the day of his death he took a continuously active part in many phases of the council's work.

During the war, in spite of the many claims upon him to carry out the work of his medical colleagues serving in the Army, and the onerous duties of a responsible post in the Special Constabulary, he found time and energy to give 567 lectures to over half a million officers and men, often travelling night and day. His force and vitality were such that an address by him had an impressive and lasting effect on his hearers. Sir Alfred Keogh, Medical Director-General of the Army in 1917, in referring to the serious position in the Army caused by

venereal disease; thanked Mr. Turner for the "yeoman services he had performed." After the war, with the vivid recollections of these services in their minds, the military authorities invited Mr. Turner to undertake a month's tour of the British Army on the Rhine. In three to four lectures a day he addressed the complete force of over 12,000 men, with the result that an immediate and considerable decrease in the number of cases of venereal disease occurred. A firm believer in the efficacy of public enlightenment in securing the reduction of venereal disease, Mr. Turner completed last year the objective he had set himself of addressing over one million men. He was active in promoting other aspects of the campaign. As the representative of the British Medical Association, and as chairman of the medical committee of the council from 1919 to 1922, he pressed with success for the inclusion of syphilis and gonorrhoea among those subjects on which the General Medical Council require questions set in the qualifying examinations. He also took part in negotiations between the Ministry of Health and the council in an endeavour to provide better facilities in rural areas for the diagnosis and treatment of venereal disease through the encouragement of specially qualified general practitioners. At his instigation in 1921 a letter was issued by the council to 23,000 general practitioners asking their personal co-operation in the council's work. He took a prominent part in the negotiations between the Society for the Prevention of Venereal Disease and the N.C.C.V.D. During 1923 and 1924, as senior vice-president and chairman of the executive committee, heavy duties fell on him owing to the illness of the then president. Only those who were in close contact with him can appreciate the whole-hearted way in which he threw himself into the general work of the council, which was developing rapidly, both in this country and in the Empire over-seas. The death of Sir Malcolm Morris led to his assumption of the additional duty of liaison officer between the Ministry of Health and the council. In 1925 the title of N.C.C.V.D. was altered, with the consent of the Ministry, to that which it now holds. Mr. Turner always preferred the original title, as he felt the need of continued and direct emphasis on the problem of venereal disease. He concurred in the change, in view of the wider educational opportunities it afforded, but his strongly expressed point of view has done much to keep the primary objective of the council in the forefront of its programme. All members, particularly the officers and members of the executive, will feel Mr. Turner's death, not only as a great blow to the social hygiene movement, but as the loss of an outstanding personality The privilege of being associated with him in this work since its inception will remain an inspiration in the future.

Dr. DANIEL E. EVANS of Swansea, who died recently, aged 63, received his medical education at St. Mary's Hospital Medical School, and graduated M.B.Lond. in 1894, in which year he also obtained the qualifications of the English Conjoint Board; he graduated B.S.Lond. in 1895. He practised in Swansea for over thirty years, and was senior physician to the Swansea General Hospital and consulting physician to the Clydach Hospital. Dr. Evans was a medical referee under the Workmen's Compensation Act, and physician and cardiologist to the Welsh Region of the Ministry of Pensions. He was a lieutenant-colonel in the R.A.M.C.T., and was in command of the 3rd Welsh Field Ambulance during the war. He took great interest in the work of the British Medical Association, was secretary of the Section of Pathology at the Annual Meeting of the Association in Swansea in 1903, and had filled the offices of chairman and honorary secretary of the Swansea Division; he was also an ex-president of the Swansea Medical Society. He is survived by a son and three daughters.

Dr. WILLIAM ELDER, a well-known practitioner of Leith, died in a nursing home at Edinburgh on July 2nd. He was born at Carnwath, Lanarkshire, in 1865, and after a preliminary education at the Knox Institute, Haddington, studied medicine at Edinburgh University, and graduated M.B. in 1885. On taking the degree of M.D. in 1896 he received a gold medal for his thesis on "Aphasia and the cerebral speech mechanism," which was published in book form in 1897. He joined the Royal College of Physicians, Edinburgh, as a Member, in 1893, and proceeded to the Fellowship in 1894. Immediately after graduation he occupied the post of house-physician to the late Professor Wyllie, and afterwards held various assistantships in Kirkcaldy, Manchester, and Leith. For many years he acted as physician to the Leith Hospital, and made numerous contributions to current medical literature. Among these were a book entitled *Studies in Psychology*, published in 1927, and articles on life assurance, on cerebro-spinal meningitis, and on agraphia and the question of the existence of a special graphic centre. *In 1904 Dr. Elder married Miss E. R. Henderson*, M.B., Ch.B., by whom he is survived.

The death took place in a nursing home at Edinburgh, on June 27th, of Dr. THOMAS MARTIN, who was a well-known practitioner in Peebles. Dr. Martin was a son of the Very Rev. Thomas Martin, D.D., formerly parish minister of Peebles, and was born in 1891. He graduated at the University of Glasgow with honours in 1912, and during the war served in the East as a captain in the R.A.M.C. Taking up practice in Peebles immediately after the war, he had become a very popular practitioner in the district, and was visiting physician to the Peebles Hydropathic. Up to a week before his death he had been attending to his practice as usual.

Medical News

The president and officers of the Section of Hydrology and Climatology of the Annual Meeting of the British Medical Association at Eastbourne have arranged a reception to Dr. Carl Haberlin, physician to the Marine Hospital at Wyk-auf-Föhr, near Heligoland. It will be held in the Saffrons Room, Eastbourne, on Wednesday, July 22nd, at 5.30 p.m. Dr. Haberlin, who is to open a discussion on the following day in that Section, on the treatment of delicate children at the seaside, will give some account of the organization in Germany. Medical men interested in the medical development of British seaside resorts, especially for children, are invited to meet Dr. Haberlin.

The Mayor and Mayoress of Leamington Spa, Alderman R. F. Bury, M.R.C.S., and Mrs. Bury, gave an "At Home" in the Pump Room, on Sunday, June 28th, to meet the Warwickshire members of the British Medical Association. Two hundred and fifty members and their friends accepted, and were shown over the new bathing establishment. Demonstrations of the various forms of balneological, electrical, and accessory treatments were demonstrated.

St. Thomas's Hospital old students' dinner will take place on Friday, October 2nd, at the May Fair Hotel, Berkeley Street, W., with Mr. J. Herbert Fisher, F.R.C.S., in the chair. The portrait of Sir Cuthbert Wallace, painted by George Harcourt, R.A., will be presented by the chairman.

At the meeting of the National Smoke Abatement Society, to be held on Thursday, July 16th, at 71, Eccleston Square, Westminster, at 3.15 p.m., an address will be given by Mr. W. Prescott, of the Federation of British Industries, on "Smoke abatement from the manufacturers' point of view." The annual conference of the society will be held in Liverpool from September 18th to 20th.

The thirteenth annual meeting of the Mental Hospitals Association will be held in the Council Chamber of the Guildhall, London, on Wednesday, July 15th, at 11 a.m.

The Royal Society of Tropical Medicine and Hygiene announces that the Chalmers Medal, founded in memory of the late Dr Albert Chalmers, has been awarded to Dr N Hamilton Fairley for distinguished original work in tropical medicine, particularly in the field of serology of helminthic infections

At the meeting of the Society for the Study of Inebriety, on July 14th, at 11, Chandos Street, Cavendish Square, a short presidential address on the aims and work of the society will be delivered, at 4 p m , by Lady Barrett, after which Sir Malcolm Delevingne will give an address, entitled " Drug addiction as an international problem "

Detailed information about the lectures and demonstrations arranged for next week by the Fellowship of Medicine and Post Graduate Medical Association will be found at page 36 of the *Supplement* A course in medicine, surgery, and the specialties will be given at the Miller General Hospital from July 20th to August 1st , fee £3 3s A course in urology will be given at the All Saints' Hospital, Vauxhall Bridge Road, from August 4th to 29th, fee £2 12s 6d From August 17th to 29th a course in diseases of children will be given at the Queen's Hospital for Children Hackney Road , fee £2 2s Courses in September will include diseases of the chest at the Brompton Hospital, psychological medicine at the Bethlem Royal Hospital, diseases of infants at the Infants Hospital, ophthalmology at the Central London Ophthalmic Hospital, general medicine and surgery at the Westminster Hospital followed by a similar course at the Metropolitan Hospital Syllabuses and tickets for all the courses may be had from the Fellowship of Medicine, 1, Wimpole Street, W 1

Mr Duncan Fitzwilliams presided at the forty ninth annual dinner of the West London Medico Chirurgical Society, which was held in the Trocadero Restaurant on July 1st Proposing the toast of the society, Dr R A Young said that the members were proud of its library, its annual lecture, its medal, its " film evenings," and its journal He paid a tribute to Charles Keetley, the pioneer and moving spirit of early days In reply the chairman referred especially to Mr Percy Dunn, the founder of their journal and its editor for many years Dr Gerald Slot proposed the toast of the guests and kindred societies, remarking that associations like the West London Medico-Chirurgical Society were essentially the province of the general practitioner , they did not aim at being learned societies, but they formed centres at which the average medical man was given an opportunity of freely discussing his experiences Dr David Ross replied in a characteristic speech , he was followed by Mr Campbell Lee, who said that the laity admired the medical profession for its service and its science The health of the chairman was proposed by Sir Henry Simson, who referred to the forceful personality of Mr Fitzwilliams, and also to the aptitude of his right hand in the realms of pugilism and physic From personal experience of both he could vouch for unwavering skill and execution

The first meeting of the International Association for Preventive Paediatrics will take place at The Hague on Monday and Tuesday, September 7th and 8th The subjects for discussion are to be " Return cases of scarlatina " and " The mortality of the first ten days of life " Further particulars of the Union Internationale de Secours aux Enfants, Geneve, can be obtained from the secretary, Professor G Scheltema, 14a, Poelstraat, Groningen, Holland

The annual meeting of the German Pharmacological Society will be held in Vienna, in conjunction with that of the Society for Diseases of Metabolism and Digestion, from September 20th to 23rd The following subjects will be discussed enteral and parenteral absorption, introduced by Drs Mansfeld of Funfkirchen Pecs, Nonnenbruch of Prague and Chiarmont of Zurich Further information can be obtained from Professor W Lipschitz, Pharmakologisches Institut, Wingertstrasse 3, Frankfort on-Main

Excellency Geheimrat Braumler, the Nestor of German physicians celebrated his ninety fifth birthday on May 13th

The sixth Natural Science Congress of the Dutch Indies will be held at Bandung, Java, from September 22nd to 23th It will consist of six sections, one of which is medical

On June 24th Dr F J Waldo completed thirty years' service as coroner for the City of London and Southwark

Dr Norman Jennings of the Middle Temple was called to the Bar on June 17th

The issue of the *Practitioner* for July is a special number devoted to fractures and accidents , it includes twenty signed articles, and a general introduction by Sir Robert Jones

The first two numbers of the ninety fourth volume of the *Archiv für Psychiatrie* have been dedicated to Professor Ernst Meyer of Königsberg on the occasion of his sixtieth birthday

The issue of the *Progrès Medical* for June 30th reproduces contemporary eulogies by Daremberg, Pasteur, Renan, and Zola on Littre, the celebrated lexicographer and translator of the works of Hippocrates, on the occasion of the fiftieth anniversary of his death

In 1930 the lowest diphtheria death rate in the ninety-three cities of the United States with a population of over 100,000 was reached, the rate being a little more than half that obtaining five years before

Dr Marcellino Pascua, hitherto head of the department of sanitary statistics, has been appointed director general of public health in Spain

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C 1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines)

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements etc), *Articulate Westcent London*

MEDICAL SECRETARY, *Medisecra Westcent, London*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams *Bacillus, Dublin*, telephone 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens Edinburgh (telegrams *Associate, Edinburgh*, telephone 24361 Edinburgh)

QUERIES AND ANSWERS

Oxaluria

" INQUIRER " (Kenya) writes I should be glad to know if any recent work has been done on oxaluria What are the conditions, in addition to an excessive consumption of oxalate containing foodstuffs which cause an excretion of oxalate crystals? I have a patient who, for no apparent reason and without any change of diet excretes quantities of oxalates with much sign of bladder irritation and some mild renal colic at intervals of years Is the error of metabolism understood? Is there any drug or treatment calculated to arrest it? Are magnesium salts of any value? Where are the crystals formed—is it in the kidney or in the pelvis? Will consumption of liquid keep it in solution, and are alkaline fluids definitely better than ordinary water? What other foodstuffs carry a heavy oxalate content besides spinach rhubarb beetroot figs and chocolate? I have failed to find the information I need in any of the books of reference to hand

Mammary Abscess

Dr. A. C. F. HALFORD (Brisbane) writes: With regard to etiology, your correspondent, "Suburban G.P." (March 14th, p. 480), might inform us if any of the babies nursed by the affected mothers suffered from ophthalmia, however mild. A purulent ophthalmia contracted from the genital canal at birth is, in my opinion, a frequent cause of mammary abscess. The infecting agent gains in virulence by the passage through the new host, and may even be responsible for a morbid puerperium not uncommonly ascribed to auto-infection. In a maternity home or hospital the infection in the baby, regarded lightly by the attendants, may be responsible for infection in other patients. The remark that "it may be months before the mother recovers" from the abscess is a grave reflection on modern treatment. I have for years endeavoured to awaken the aseptic conscience to the fact that an abscess is the terminal phase of an infective process, and that therefore recovery from any form of abscess should result in from ten to fourteen days. Localization means in every case that the besiegers have been trapped and rendered *hors de combat* by the besieged. They may be allowed to leave the field, but not with all the honours of war, and care must be taken that no reinforcements meet them at the gate of exit in the shape of a secondary infection. This can only be prevented by the careful application of an antiseptic dressing into which the evacuating matter is received and destroyed. No antiseptic should be applied to the abscess cavity, as that action would retard the healing process which should inevitably follow.

Income Tax

New Partnership—Cash Basis

"ALPHA" took in a new partner, B, as from January 1st, 1930. B is entitled to one-third share of the profits, and bought a corresponding share in the debts outstanding at December 31st, 1929. In computing the assessment for 1931-32 to be based on the amount of the practice profits for 1930 the inspector of taxes declines to accept the cash receipts as a sufficiently correct measure of the gross income, claiming to bring in the increase of the book debts at December 31st as compared with January 1st, 1930.

*** In law the inspector is right, and from that standpoint "Alpha" has no sufficient defence for the employment of the cash basis. But the official practice is to accept that basis if there are no special circumstances going to show that the cash receipts do not fully reflect the true gross income of the practice. It is possible that the employment of an additional principal in the practice may increase the gross earnings. If this is so the cash receipts for 1930 will be less than the true—though partially unrealized—earnings for that year, and in such circumstances the cash basis cannot be successfully resisted. If that is the case we suggest that "Alpha" should have a personal interview with the inspector and explain to him the special difficulty of estimating the *value* of the outstanding debts, with a view to agreeing, if possible, on a rough basis of estimating probable losses through non-recovery of bookings.

Use of Car for Private Purposes

"A. P. B." uses his car "a little" for private purposes, and when making his return claimed to deduct only four-fifths of the cost of petrol and repairs. The inspector claims that the deduction for other car expenses should also be restricted to four-fifths. If he were not in practice "A. P. B." would not keep a car.

*** The total expenses will have to be restricted according to the proportion of professional to total use. It may, of course, be that one-fifth of the petrol and repair costs represents a fair charge for private use, but the better line of argument would be to show that the ratio of professional to private use is, say, as 5 is to 1, and claim to deduct five-sixths of *all* expenses. The fact that a car would not be kept if he were not in practice does not assist our correspondent; the point has to be dealt with on the facts as they are.

Motor Car Transaction

"D" bought a car for £375 in December, 1929, and sold it for £190 when giving up his practice in January, 1931. What can he claim for depreciation?

*** The amount of depreciation allowable is 20 per cent. (or 15 per cent.) on £375 as for the year 1930-31—or rather for the proportion of that year from April 5th, 1930, to the date when he gave up the practice. The claim should be made when the declaration of income is rendered, but will probably be admitted by the authorities as part of the adjustment of liability following on the transfer of the practice.

Car Replacement and Depreciation Allowance

"K. M." states that he has hitherto claimed and been allowed the cost of replacement of his car, but now expects to retain his present car in use for some years. Should he claim depreciation-cum-obsolescence allowance in future?

*** Yes, with the exception that he cannot claim to be allowed for depreciation of a car as for a financial year the assessment for which has been reduced by a cost of replacement deduction. For example, suppose "K. M." replaced his car in 1930 and was allowed £150 therefor in calculating his profits for the year ended December 31st, 1930. In that case his assessment for 1931-32 will be £150 less than would have been the case if the cost of replacement had not been allowed, and his depreciation claim will have to be deferred until 1932-33.

LETTERS, NOTES, ETC.

Treatment of Carbuncle

Dr. C. H. MARTIN (Burnie, Tasmania) writes: Your correspondents on the subject of glycerin as a surgical dressing may be interested in the following method of treating carbuncles, which I have been using for a number of years. A piece of lint, a good deal larger than the inflammatory "...e carbuncle, is obtained and folded twice the angle thus formed, a piece is cut, making a hole in the lint just big enough for the carbuncle to poke through. The larger piece is spread thickly with ichthyol in vaseline (50 per cent.) and applied to the skin round the carbuncle. The smaller circular piece is soaked in glycerin ac. carbol. (10 per cent.) and applied to the carbuncle itself. The whole dressing is then covered with oiled silk and cotton-wool, and bandaged. The ichthyol part is changed once daily, the glycerin part frequently, by applying fresh disks of soaked lint. The process is persisted in until healing is complete. Patients have assured me that relief from pain is rapid and maintained. The pus softens, free drainage is soon established, and the slough separates in a few days, leaving a clean cavity with healing edges. The relief is quite dramatic, and appears to be due to the extensive lymph flow, induced by the glycerin, quickly relieving the local tension. Local reinfection is apparently prevented by the ichthyol.

Testimonial to Sir Ronald Ross

Further contributions to the Ross Award Fund, amounting in all to £77 9s. 11d., have been received between October 31st, 1930, and June 30th, 1931. The contributors include J. C. De La Cour, Jesse Grell, James Hargreaves, Johnston Family Trust (second donation), Mrs. M. K. Marsden, Mrs. Partridge, Mrs. Webster, and Lord Winterton. The total amount so far received in response to the appeal is £14,406 17s. 6d. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

A Warning

A correspondent informs us that "a young man on the make," representing himself to be a doctor, has lately visited medical practitioners and hospital staff quarters on the south coast of Devon. Any reader who receives a call from him might do worse than communicate with the superintendent of the Teignmouth Police.

The Headmaster of the Westminster Abbey Choir School wishes to bring to the notice of members of the medical profession the fact that there are vacancies from time to time at that school for boys who can sing, and can pass a simple entrance examination. The fees are very moderate, and boys are prepared for the common entrance examination for public schools.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 46, 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenents at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 35.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

20 Hyperinsulinism

G. H. TUTTLE (*New England Journ. Med.*, May 14th, 1931, p. 1039) doubts whether the pancreas is the sole source of insulin production, and discusses two cases which seem to support his view that the tissues can also function in this way. He points out that, if the pancreas alone is concerned in the supply of insulin, the condition of hyperinsulinism can only be brought about in one of two ways: (1) as the blood sugar rises it stimulates a centre in the vagus nucleus which transmits impulses through filaments of the right vagus nerve directly to each cell of the islands of Langerhans, causing an outflow of pancreatic insulin in the blood; and (2) the acid food from the stomach excites certain hormones, probably secretin, present in the duodenal mucosa, and these exert a specific action upon the islet cells, bringing about the discharge of pancreatic insulin into the blood. If the blood stimulus is not sufficient to restrict the blood sugar content within normal limits after each meal, the rising blood sugar stimulates the brain centre, and causes the production of additional supplies of insulin by transmitting impulses through the right vagus nerve to the cells of the islands of Langerhans. Tuttle has shown that large amounts of glucose can be utilized daily by depancreatized dogs, and he has hypothecated the existence, therefore, of insulin derived from the tissue cells. In the two cases discussed by him in the present report there was association of cancerous growths with marked hyperinsulinism, though the pancreas was normal; he adds that, in any case there seems to be an intimate association between the presence of malignant disease and the production of insulin by the tissues.

21 A. D. CARR *et al.* (*Journ. Amer. Med. Assoc.*, April 25th, 1931, p. 1363) report the case of a youth, aged 19, who suffered increasingly from attacks similar to the syndrome resulting from an overdose of insulin; they were relieved by the ingestion or intravenous administration of dextrose, but medical treatment did not clear up the condition and the symptoms progressively increased. A localized tumour of the pancreas was found and removed, and complete recovery ensued.

22 Etiology of the Common Cold

D. F. MILAM and W. G. SMILLIE (*Journ. Exper. Med.*, May 1st, 1931, p. 733) report the results of studying the incidence of nasal catarrh on an isolated tropical island in the West Indies, this being part of a series of investigations of colds occurring in isolated communities and under different environmental conditions. Environmental factors seemed to be more important than the known bacteriological concomitants, and the authors agree that the specific originating factor is as yet unknown. The incubation period is about three days, and the infection seems to be spread by contact. The secondary and more severe symptoms associated with colds are due to certain aerobic bacteria, commonly found in the nasopharynx. Of the environmental predisposing factors the most potent appeared to be a fall in the atmospheric temperature, and the seasonal incidence curve of acute colds in the island corresponded with that of the United States mainland. Although the usual high tropical prevalence of haemolytic streptococci was noted, this seemed to be of no etiological significance in the case of nasal catarrh, nor was the similarly common bacillus of Friedländer concerned. The authors remark that in the temperate zones changes in the seasonal temperature are more abrupt, and colds are more severe, as compared with the tropical countries, where both temperature changes and colds are mild.

23 Cistern Puncture

L. JACOBI (*Med. Journ. and Record*, May 6th, 1931, p. 451) advocates cistern puncture in the upright position, using the neck compressor, designed by Benedek and v. Thurzo, over the internal jugular veins to insure a positive intracisternal pressure. The compressor consists of an elastic band carrying two pads, which are applied 0.5 to 1 cm. below the thyroid cartilage, and 3 to 3.5 cm. from the middle line, fitting exactly over the veins which lie behind the anterior border of the sterno-mastoid muscle. The bandage is then pulled sufficiently tight to obtain venous stasis above it without discomfort to the patient. Within fifteen to thirty seconds the face becomes suffused and the veins prominent, and these signs should be well marked before the dura is punctured. With the patient erect and the head lightly flexed, the fluid, since it is under pressure, drains out immediately the dura is pierced; the method has the advantage of being able to ensure a positive pressure, thus avoiding a dry tap in every case, whereas in the horizontal position a dry tap may result when the pressure is low. With the patient sitting in the upright position both the facility and the safety of the procedure are enhanced.

24 Myopathic forms of Polyneuritic Syndromes

L. BÉRIEL and A. DEVIC (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, May 18th, 1931, p. 732) draw attention to certain benign myopathies with a polyneuritic syndrome. Observation of many cases has convinced them that there exists a neuro-muscular form of epidemic encephalitis. The curious distribution of this type of case (rare in Paris and frequent in the South-East of France) has given rise to differing opinions as to the etiology. The authors suggest that the frequency of the cases in the South-East is due to some undetected focus of infection there, possibly a mild epidemic encephalitis. From the point of view of prognosis the authors emphasize the importance of correct diagnosis, these cases being benign; even after two or three years of paralysis the patient may recover completely. All these patients exhibit extreme difficulty in sitting up when they are in bed, and they may be unable to turn over. In the more severe forms they lie utterly inert, although capable of a certain motility of the extremities of the limbs. Complete cure is usual, and amelioration sets in generally after several months. Occasionally the duration is longer, but the prognosis is still good. A case is quoted of a girl, aged 15, who slowly developed paralysis of the muscles of the shoulder and pelvic girdles. After several months a total paralysis invading the trunk and limbs gradually appeared. At this stage the patient presented the picture of an acute myopathy. Very gradually she began to recover, and about six months after the onset she could sit up in bed, but could not feed herself. This condition lasted one year. Gradually the use of her arms returned, and finally, nearly three years after the onset, she was in normal condition except that all reflexes were abolished.

25 The Salivary Secretion in Mumps

N. R. SCHASTIN (*Jahrb. f. Kinderheilk.*, May, 1931, p. 304) reviews the literature, including the recent paper by Rocchi (*Epitome*, December 28th, 1929, para. 588), and records his observations made in Krasnogorki's Children's Clinic at Leningrad on the salivary secretion during mumps in children. His conclusions are as follows. Systematic investigations show a diminution of the salivary secretion during mumps. This particularly applies to cases in which the secretion was examined before the attack of mumps, as well as to cases in which only one of the salivary glands was affected, and a comparison could be made of the secretion of the healthy and diseased glands. The duration and degree of diminution of the salivary

secretion differed for each gland. The secretion sank to the lowest level, and almost entirely disappeared in the case of the gland which was first affected. The minimum secretion for each individual gland was found on different days. The salivary reflexes disappeared in the gland which was first attacked by mumps. At the end of the first week, however, they reappeared, and then gradually reached their original level. The recovery of activity of the parotid gland first affected is extremely slow, and is not complete after all the clinical symptoms of parotitis have subsided, while in the other gland recovery takes place more rapidly. Return of the normal secretion of the affected parotid gland takes twice as long in myxoedema as in ordinary children—namely, fifty-four days instead of twenty-one to twenty-seven days. The remarkable diminution in the secretion of the gland first affected is a diagnostic feature of mumps. At a certain stage of the disease there is a diminution in the amylase content of the saliva, but this soon disappears. Variations in the content of the inorganic and organic substances in the saliva barely exceed the normal limits.

26 Diphtheria in Uruguay

M. RUBINO, A. J. J. LEUNDA, and J. MOREAU (*Paris Méd.*, May 9th, 1931, p. 447) record their observations on an epidemic of malignant diphtheria which occurred at Montevideo in 1928. Their conclusions are as follows. Strains of *C. diphtheriae* are found in Uruguay with as high a toxic power as that of the toxigenic organism of the Institut Pasteur or Rockefeller Institute. This high toxic power can explain several cases of malignant diphtheria. Certain cases of clinically mild diphtheria were found which were cured with a small dose of serum, although they were due to bacilli possessing a very high toxigenic power. On the other hand, there were cases of malignant diphtheria which yielded bacilli with a low toxigenic power. No exact relationship was found to exist between the morphological type of *C. diphtheriae* and its toxigenic power.

27 Relapsing Fever in Children

FU-T-ANG CHIN, S. DEITRICK, and SHI-FAN CHUNG (*Nat. Med. Journ. China*, April, 1931, p. 224) record their observations on 26 cases of epidemic relapsing fever in Peiping occurring in children aged from 8 to 12 years. A widespread petechial eruption was common, but it could not be regarded as a sign of relapsing fever, since insect bites were probably responsible. The leucocyte count, which varied, was of little diagnostic value. Thrombocytopenia was constantly observed during the febrile attack, but after recovery the platelet count returned to normal or nearly normal. No prolongation of bleeding or of the coagulation time was noted. The Wassermann reaction was negative in all but one case, and the globulin test was uniformly negative in fourteen cases in which it was performed. There was prompt response to arsenical treatment, the temperature falling to normal in less than twenty-eight hours. No deaths occurred.

28 Tertiary Syphilis of the Thyroid Gland

J. P. P. GUIDICELLI (*Thèse de Paris*, 1931, No. 51), who records an illustrative case in a woman aged 42, states that tertiary syphilis of the thyroid gland is a rare condition, but that probably many cases fail to be recognized, so that the possibility of syphilis should be more frequently considered in affections of this gland. No pathognomonic sign can be found on clinical examination. Since tertiary syphilis of the thyroid is most likely to be mistaken for malignant disease, a search for evidence of syphilis should be made in the presence of an apparently malignant tumour of the thyroid, and even if none can be found antisyphilitic treatment should be tried. The prognosis is good, and, except in urgent cases in which operation is needed, the treatment should be purely medical, the best results being obtained by mercury cyanide and arsenical preparations, with potassium iodide and bromide as adjuvants.

Surgery

29 Angioma of the Bladder

M. SCHILLINGS (*Rev. Belge des Sci. Méd.*, April, 1931, p. 412) records a study of vesical angioma based on 30 cases, of which one was under his own care. Age and sex appear to play no part in the etiology of this rare condition. In contrast with other vesical tumours, angiomas are usually single, and occur most frequently at the base of the bladder; their colour, ranging from bluish red to violet, is characteristic. Three varieties occur, pediculated, sessile, and infiltrated, the two latter being the most common. Angiomas are benign tumours of slow evolution, and rarely give rise to metastases. They are composed of newly formed blood vessels, and two main types occur: the simple (telangiectases or vascular naevi), characterized by a large number of tortuous capillaries, abnormally dilated and separated from each other by connective tissue; and the cavernoma, formed by blood reservoirs of variable size and irregular shape, limited by a fine endothelial membrane and separated by collagenous septa. The symptomatology of cavernoma is not characteristic; the chief symptom is haematuria, which is frequent, intermittent, and may be so abundant as to cause anaemia, or even death. Diagnosis must be confirmed by cystoscopy; the site, characteristic colour, circumscribed form, the integrity of the adjacent mucosa, and the nature of the haematuria are points in the differential diagnosis. Small angiomas are best treated by electro-coagulation. In large, pediculated, non-infiltrating angiomas, cystotomy with tumour resection is indicated; when the vesical wall is infiltrated, partial cystectomy is the treatment of choice.

30 Endothelial Myeloma

Ewing was the first to point out that there is a group of tumours, originating chiefly in the shafts of long bones, occurring mostly in children and young adults, and which differ clinically, radiologically, and histologically from osteogenic sarcomata. W. B. COLEY (*Radiology*, May, 1931, p. 627) states that this myeloma, though the most malignant of bone tumours, is both highly radio-sensitive and also responsive to the toxins of erysipelas and *B. prodigiosus*; conservative treatment is therefore justifiable for a limited period before resorting to amputation. An analysis of the end-results of different methods indicates systemic treatment with the previously mentioned toxins combined with local radiation, preferably the radium pack, as the best method of treating a primary operable case. If the condition has not markedly improved in six or eight weeks, amputation or resection, followed by prolonged prophylactic toxin treatment, should be considered. Further delay without evidence of improvement may result in the development of metastases with an ultimate fatal ending. In Coley's statistics a relatively considerable number of patients with inoperable growths were found to have recovered and remained well for five years or more; four were treated with toxins alone, and five with toxins and radiation. In six of these patients metastases had already developed. Coley advises, therefore, that all cases should be given the benefit of a thorough trial of toxin and radium treatment before being considered hopeless.

31 Pancreatic Cysts

E. S. JUDD, H. MATTSON, and H. R. MAHORNER (*Arch. of Surg.*, May, 1931, p. 838) report 47 cases of cysts of the pancreas treated surgically at the Mayo Clinic since 1921. As a rule the cyst makes its way towards the anterior parietal peritoneum in the line of least resistance, presses into the lesser peritoneal cavity, and presents between the stomach and the transverse colon, behind the gastrocolic omentum. Sometimes the cyst lies between the stomach and the liver, or protrudes into the lesser peritoneal cavity behind the stomach. It may also invaginate itself between the layers of the mesocolon, and in this case it usually presents behind

the transverse colon. A smooth, relatively immobile, hemispherical swelling is characteristic of a pancreatic cyst. In 95 per cent. of the cases under review this was felt above the umbilicus, generally between the ensiform cartilage and the umbilicus in the median line or to the left of it. Pancreatic cysts are relatively immobile, unless situated in the tail of the gland and without adhesions, when they may be freely movable. Of the patients 43 (91 per cent.) complained of pain, and in 13 cases there was evidence of cholecystitis. Associated symptoms were jaundice, nausea, vomiting, and loss of weight and constipation. The diagnosis of pancreatic cyst is confirmed by *x*-ray examination when there is a filling defect in the stomach which can be eliminated by displacing the stomach, or the displacement of the duodenum and small intestines. The ideal treatment is the complete removal of the cyst, but this is only possible in cases of a small cyst with few adhesions situated preferably in the tail of the pancreas with a narrow pedicle. When the cyst is large and adherent, and when the glandular tissue encroaches on the cyst, marsupialization is the operation of choice. Total excision was performed in seven cases, in all of which the cyst was benign ; partial excision and drainage was undertaken in six cases. Persistent discharge from the fistula made by drainage may be troublesome, and may continue for as long as two years.

32 Diagnosis of Temporal Tumours

DE MARTEL (*Rev. de Méd.*, May, 1931, p. 372) describes certain signs which facilitate the diagnosis and localization of temporal tumours. The first of these is hemianopsia. Cushing has shown that hemianopsia in the upper quadrant, or simple homonymous contraction of the upper part of the visual field, indicates a lesion of the anterior and lower portion of the opposite temporal lobe, while a lesion of the upper and posterior part of the lobe causes a similar condition in the lower visual field. From consideration of the anatomy of the optic nerves, it is shown that this diagnostic method is applicable only in commencing tumours, and in such cases perimetry can be of great value. Occipital tumours give rise to the same visual disturbances as large temporal growths. Generalized convulsions are not rare in temporal neoplasms, but have no localizing value. The unciform crises described by Jackson are associated with temporal tumours bordering on the hippocampal uncus. They consist of olfactory or gustatory sensations ; these are usually disagreeable, and are often associated with visual hallucinations, which are relatively frequent and of great localizing significance. Complex visual hallucinations are indicative of temporal trouble, while simple ones are most often associated with occipital lesions. Wernicke's aphasia is present in left temporal growths ; in this condition the patient, though articulating easily, is unable to say what he wishes, and understands commands imperfectly and executes them badly. De Martel briefly notes the difficulty of differentiating temporal from occipital tumours, and advises ventriculography in doubtful cases.

33 The Surgical Treatment of Chronic Obstructive Jaundice

P. BAUZET (*Paris Méd.*, May 16th, 1931, p. 478) recommends early operation in these cases. A stone in the common bile duct should be readily recognized, from the history, clinical signs, *x*-ray and laboratory examinations. Even if cancer of the pancreas is diagnosed, the author recommends early operation, partly because laparotomy may show the condition to be due to a stone in the common bile duct or to an operable cancer of the ampulla of Vater, and partly because biliary anastomosis, permitting the passage of the bile directly into the alimentary canal, results in considerable improvement to the patient ; the jaundice and itching disappear, the urine clears, the stools regain their normal colour, weakness diminishes, the appetite returns, the patient puts on weight, and life is prolonged for twelve to eighteen months. The author prefers a cholecysto-gastrostomy to a cholecysto-duodenostomy. Under local anaesthesia a median incision gives access to the distended gall-bladder, which, punctured and emptied of its contents, is readily apposed to the anterior wall of the pyloric antrum. A vertical incision through the stomach wall preserves intact the circular muscular fibres which will form a sphincter preventing the reflux of gastric contents into the gall-bladder. The opening need not be large. The anastomosis is performed on a Nélaton's or Pezzer's sound. Shock is practically absent, and improvement is rapid.

34 Transplantation of the Epiphyseal Cartilage Plate

From a previous series of experiments on the transplantation of the epiphyseal cartilage plate, S. L. HAAS (*Surg., Gynecol. and Obstet.*, May, 1931, p. 958) concluded that this plate, either alone or with an adjoining piece of the epiphysis or diaphysis, lost its power to produce length growth. Heller, Fohl, and other authorities are not in agreement with this conclusion. In order to present further evidence for or against this operation, Haas performed another series of experiments on young growing rabbits. The results confirmed his former findings, and he maintains that unless more definite evidence is presented to prove the viability of the epiphyseal cartilage after transplantation, such transplantation in man with the expectation of obtaining length growth is not justified. Haas adds that it is difficult to explain the discrepancies between his findings and those of other investigators such as Heller ; technical errors or misinterpretation of results may possibly account for the variations, and further study is urgently necessary by other workers in view of the clinical considerations which are entailed.

Therapeutics

35 Symptomatic Treatment of Narcolepsy

J. B. DOYLE and L. E. DANIELS (*Journ. Amer. Med. Assoc.*, April 25th, 1931, p. 1370) report the successful treatment with ephedrine sulphate of six patients suffering from narcolepsy. Five were completely relieved, and the sixth was markedly improved. Since ephedrine is productive of insomnia during the early hours of the night, it has been the authors' practice to prescribe relatively small doses of the drug in the late afternoon. They point out that ephedrine is a more valuable antidote to morphine poisoning than is caffeine. The doses of ephedrine given in the narcoleptic cases ranged from 3/8 grain, three times daily, to 1½ grains. They add that thyroid medication in the treatment of narcolepsy has not been generally satisfactory, but the employment of pituitary substance for this disease appears to be worthy of further study.

36 Treatment of Angina Pectoris by Stovaine Injections

L. LANGERON (*Presse Méd.*, April 11th, 1931, p. 521) refers to the work of Lemaire, who showed that visceral pain in general might be relieved by the injection of an analgesic into the peripheral region to which the pain was referred. He has applied this principle in the treatment of angina pectoris, and has given injections of stovaine to three patients suffering from this syndrome. A solution of stovaine (1 in 100) was injected under the skin at the site of the most severe pain, 10 c.cm. being the usual dose. The first two patients showed no evidence of organic heart disease, but were accustomed to more than moderate amounts of alcohol and tobacco. Very definite relief followed injections of stovaine, although nitrites, iodide, and morphine had previously been employed without success ; this improvement was subsequently maintained. The third patient was older, and the subject of hypertensive and atheromatous disease ; the development of the syndrome in his case suggested myocardial infarction. Stovaine injections were given, but without effect, and the patient died on the following day. It appears that this drug is valuable in patients suffering from angina pectoris due to coronary spasm, but that it is useless where a coronary lesion is largely or wholely responsible for the symptoms. The author believes that stovaine acts not

valvular disease, including 131 cases of mitral stenosis, while 137 patients had a rheumatic history. Adopting the American Heart Association functional classification, it was found that patients in Classes I and II*a* as a rule did well and had normal pregnancies and labours; those of Classes II*b* and III needed careful supervision, and as a rule prolonged rest in hospital. The mortality rate was 5 per cent., and there were only five Caesarean sections. Rest, diet, and general hygiene were found to be of greater importance than drugs in treatment. Labour should be rendered as easy as possible by use of sedatives and intermittent anaesthesia; quickness in delivery is not so important as easiness. During the third stage manual stimulation of the uterus should be avoided, and ergot is safer as a haemostatic than pituitary extract. Induction of abortion, rarely to be considered in primiparae, is employed with diminishing frequency as antenatal supervision improves; in advanced cardiopathic cases, until a good degree of compensation has been re-established, it may do much harm. Lactation should usually be encouraged. Very prolonged medical observation must follow the puerperium, for permanent impairment of the cardiac efficiency is a possible sequel. As a rule three years' sterility is desirable after pregnancy, but in working-class practice the use of the condom is the only reliable contraceptive measure.

49 Use of Narcotics in Obstetrics and Gynaecology

J. B. DELEE (*Journ. Amer. Med. Assoc.*, March 28th, 1931, p. 1007) briefly reviews the indispensable uses of narcotics in obstetrics and gynaecology. Pregnancy does not contraindicate the exhibition of narcotics for any purpose which demands them. The child does not suffer, except from an overdosage that would endanger the mother. Morphine is indicated when pregnancy is associated with an acute abdominal condition, also to prevent abortion from any cause. During labour DeLee considers opium preparations preferable to chloral, barbituric acid compounds, and sodium amytal. When narcotics are given in labour at the right time and in proper dosage the child is not endangered, and the mother is made more resistant to exhaustion, acidosis, shock, and post-partum haemorrhage. By conserving her strength in a prolonged first stage, narcotics actually shorten the second, and prevent difficulties in the third; the puerperium is more smooth, convalescence more rapid, while infection is less likely since the woman's immunity powers have been preserved. In eclampsia, placenta praevia, post-partum haemorrhage, morphine is invaluable; its value is equally great as an aid to general anaesthesia. Before gynaecological operations morphine has its uses, but barbituric acid preparations, tribromethanal, and other drugs have recently been used. Morphine reduces the amount of general anaesthetic required, and obviates to an appreciable extent the incidence of post-operative complications. With the exception of cancer, morphine has but limited uses in chronic gynaecological diseases.

Pathology

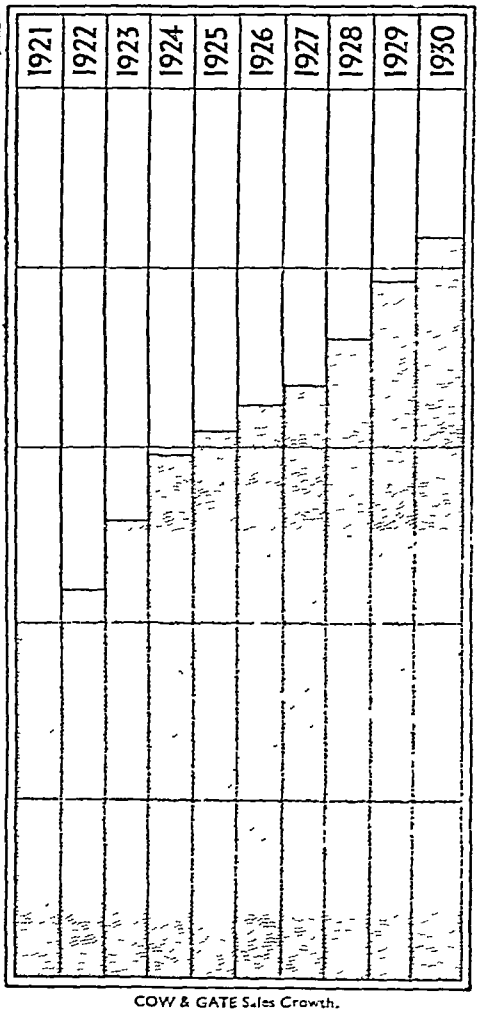
50 Meningeal Reaction to Therapeutic Serum

Little mention has been made of the effect of injected serums on the nervous structures, though their reaction on other tissues has been fully discussed. W. M. SHEPPE (*Amer. Journ. Clin. Path.*, January, 1931, p. 77) reports a case in which accidental infection with the meningococcus occurred in a laboratory. The patient was treated with anti-meningococcal serum, but the reaction was fulminating, and marked by most severe clinical symptoms. It did not present the usual characters of immediate, generalized serum reactions, and all the symptoms pointed to severe meningeal irritation. Evidently a localized allergy involving the nervous system had developed; which supposition is substantiated by the fact that a repetition of the reaction followed the injection of a minute quantity of serum (0.1 c.cm.) intravenously. As the result of work on the spinal fluid of a treated case of meningococcal meningitis, Sheppe suggests that the reaction was due to the irritation of the meninges by the formation of precipitins in the presence of an excess of precipitinogen (horse serum), and describes a method for the detection and prevention of impending meningeal reactions. The literature relating to the action of serum on the nervous system is briefly reviewed.

51 Bence-Jones Proteose in Multiple Myeloma

A. MAGNUS-LEVY (*Deut. med. Woch.*, April 24th, 1931, and May 1st, 1931, pp. 703 and 751) found that the Bence-Jones proteose excreted by a patient with multiple myelomas was proportional to the amount of protein in the diet, and that the Bence-Jones nitrogen portion constituted 42 per cent. of the total nitrogen content in the urine, whether the absolute total was high or low. He considers that protein metabolism is the most important factor in determining the amount of Bence-Jones proteose excreted, and concludes that the diet should contain 60 to 70 grams of protein in excess of the amount which is being excreted in the urine as proteose, in order to maintain nutrition. There is no evidence that the Bence-Jones proteose is formed elsewhere in the body than in myelomatous tissue, with the possible exception of bone marrow, which may produce very small amounts. The greater part of normal serum protein probably originates in the bone marrow, but the connexion between this and such abnormal nitrogenous bodies as the Bence-Jones proteose has not yet been elucidated. The damage to the kidneys, joints, and other organs which occurs in cases of myeloma is secondary, and due to the circulating Bence-Jones proteose. Magnus-Levy considers that there is good evidence that the abnormal metabolism in this condition is related to the formation of the amyloid substance, the Bence-Jones proteose being probably one of its several possible precursors.

52 Functional Tests in Renal Disease



C. HOLTEN and P. B. REHBERG (*Acta Med. Scand.*, April 15th, 1931, p. 538) have observed 50 patients with various forms of nephritis, and conclude that reduction in the renal filtration rate is associated usually with diminished concentration; 41 patients had various types of nephritis, 5 had hypertension, and 4 had "surgical" kidney. While glomerulo-nephritis, nephrosclerosis, and amyloid disease reduce filtration proportionately to the gravity of the case, this reduction occurs but rarely in nephrosis. Functional tests indicate the renal excretory power, and retention symptoms do not occur when filtration does not fall below 50 per cent. of the normal; when it was reduced below 30 per cent. uraemic symptoms appeared and persisted until the nitrogenous diet was restricted. Conversely, patients with a much lower filtration rate may be freed from symptoms indefinitely by such restriction. Filtration tests, indicating the degree of protein tolerance, are a guide to treatment. In suitable cases the administration of large quantities of fluid aids the urea excretion and thus maintains a moderate level of blood urea. Rest appears to aid filtration, while over-exertion and intercurrent infections retard it. Filtration determination is of great prognostic value in uraemic and non-uraemic cases, and the patient's progress can be gauged.

53 Passage of Hormones through the Placenta

L. CATTANEO (*Ann. di Ostet. e Ginecol.*, March 31st, 1931, p. 253) records experiments showing that adrenaline, the hormone of the posterior lobe of the pituitary, and choline, injected into the foetal heart in pregnant rabbits or guinea-pigs, pass through the placenta, and after a short time manifest their characteristic effects on the maternal blood pressure. Extirpation of the maternal suprarenal glands, however, led to death in pregnant as well as in non-pregnant animals, but survival occurred if a fragment was left which weighed only half as much as the foetal suprarenal tissue. It is inferred that the adult suprarenal gland contains some principle which is lacking in that of the foetus.

Facts WHICH SPEAK for THEMSELVES!

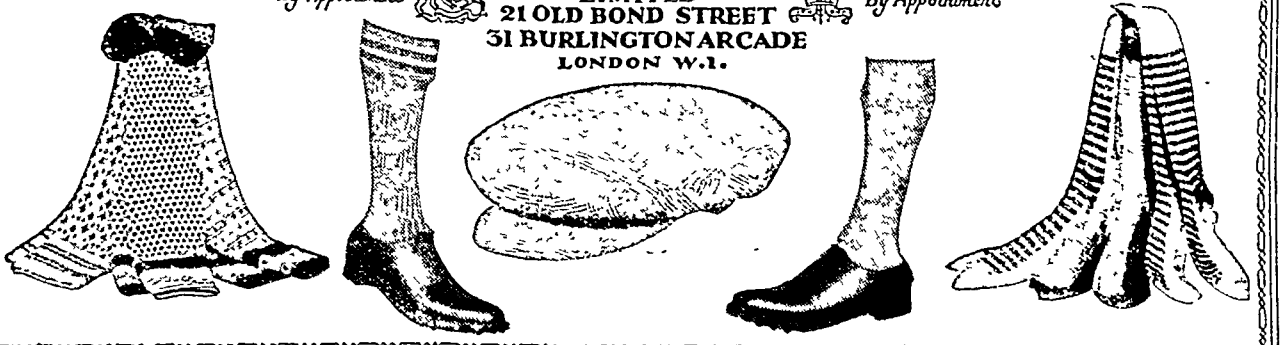
COW & GATE Sales Growth.

COW & GATE Milk Food is now supplied to almost every Hospital and Welfare Centre in this country, and it's certainly not chosen for the sake of cheapness.

We illustrate here a graph showing the COW & GATE sales growth during the last ten years.

THERE MUST BE A REASON FOR THIS EXTRAORDINARY GROWTH!

It is because the Medical Profession has over a long period proved the value of COW & GATE, and insist on having the best!!



Support Home Agriculture. COW & GATE LIMITED is an all English Firm, using only home produced milk.

Write for particulars of our special Milk Foods for difficult Infant Cases.

"The best milk for babies, when natural feeding fails"

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.
Mr R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deaf ness. Many are in use and excellent results are reported on the latter as evidenced by the interest shown at the last B.M.A. Meeting.

1. It [illegible] and the case ld.
2. It [illegible] and leaves the hands free
3. It removes strain, thus relieving head noises giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

PERFECT FOOTWEAR COMFORT IS GUARANTEED TO EVERY CUSTOMER.

Is it fair to your best friend to make him your Executor? The duties are onerous, and usually thankless; the responsibilities are great and the penalties for neglect are severe. Moreover, he may die, and the expense of appointing his successor is considerable. On the other hand, if you appoint the Westminster Bank instead, the fees (which are paid out of your estate) will probably be only a fraction of the legacy which you would have left to a private trustee.

Ask for the 'Executor and Trustee' booklet at any local branch, or call at

THE NASAL IONIZER
FOR THE
TREATMENT OF HAY FEVER

This apparatus was described by Mr. Philip Franklin in the *British Medical Journal* on June 27th, 1931. It provides a convenient and simple means of applying current from a galvanic battery or pantostat to the nasal tissues for the treatment of Hay Fever and Paroxysmal Rhinitis. The apparatus, comprising a comfortable headband carrying adjustable electrodes, a kneepad and the necessary flexes and terminals for connecting to the battery, is supplied complete—
PRICE (in box) £1 18s. 6d.

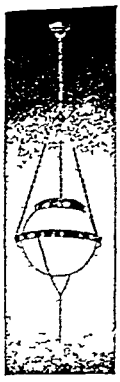
FRESH LIQUID TOILET SOAP
for each user—and
ECONOMY
for the provider
ASSURED WITH THE
DROP *by* DROP SYSTEM

Part of a Horton Liquid Toilet Soap installation at the NEW VICTORIA CINEMA.

HORTON have now produced a perfect toilet soap in liquid form; a liquid toilet soap entirely free from cocoanut oil and therefore non-irritating to delicate skins.



And further, to make the Dispensing apparatus as perfect as the liquid toilet soap, Horton have developed the ideal container in non-tarnishable oxyplatine metal incapable of forming verdigris.

Thus you have the perfect liquid toilet soap, the perfect container, and the perfect service—clean, fresh soap; served drop by drop to each user. No waste, no infection risk, no pilfering, no clogged pipes.

Save money by stating your requirements. Horton will gladly quote you by return.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the profonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, *at Llantairtechan, amidst the finest scenery in North Wales.* On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

MATLOCK.

Member of the British Spas Federation.

TREFRIW CHALYBEATE WELLS

Established over 70 years.

The richest Sulphur-Iron waters known, containing Iron as Ferrous-Sulphate, maximum dose only one ounce. Wonderfully efficacious for Rheumatoid Arthritis, Rheumatism, Sciatica, Neuritis, Anaemia, and Kindred Ailments.

SPA CURE AT HOME.

The Waters are scientifically bottled in perfectly natural Spa condition, without alteration or manipulation, and may be prescribed to patients at home just as beneficially as at the Spa. The remarkable efficacy of the home treatment, which is a very important feature of this Spa, cannot be too strongly emphasized, and is well attested by eminent medical authorities. Full particulars and sample of the Waters post free from Manageress, Trefriw Wells, Trefriw, N. Wales.

BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 Treatments. Medically certificated staff.

LEAMINGTON Advanced Spa Treatment. Saline Springs.

LLANDRINDOD WELLS The Modern Welsh Spa.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods. Restful Air.

A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Pump Room, Leamington, or to the Managers of any of the above mentioned.

Renowned for Treatment of STOMACH and LIVER DISORDERS.

VICHY FRANCE

Renowned for Treatment of GOUT, DIABETES, and OBESITY.

The waters of Vichy belong to the sodium bicarbonate group. They are generally gaseous, clear, and colourless. They are nearly all similar in composition and contain, approximately, a total of 7.5 grammes of mineral matter which includes, notably, bicarbonates of sodium, potassium, calcium chloride and sulphate of sodium, free carbonic acid, and those rare gases: argon, krypton, xenon, helium, neon, etc. At their source, the springs present differences in temperature which give a variety of physiological actions due to their peculiar vitality.

The Thermal Establishment is justly considered as a model of its kind, and every care is taken that the latest discoveries in physiotherapy may be utilised under the best possible conditions for allowing the specific action of the waters to give the most beneficial results.

The cost of a stay at Vichy is surprisingly moderate. Hotels are numerous and comfortable and range from the most luxurious to the modest pension.

Detailed information concerning the treatment at Vichy may be had by addressing the Compagnie Fermiere de Vichy, 24, Boulevard des Capucines, Paris.

SCARBOROUGH

Enjoys a dry and bracing climate, an equable temperature, large amount of sunshine and low rainfall.

As a holiday resort Scarborough offers a never-ending variety of attractions—excellent Golf, Tennis, and Bathing; good music and attractive entertainments and amusements.

June 10th, 1931.

MIDDLESEX HOSPITAL MEDICAL SCHOOL,
LONDON, W.1.

(University of London.)

The WINTER SESSION begins on October 1st, and new students should apply for admission at an early date.

The Medical School and Hospital occupy a central position within a few minutes' walk of Oxford Circus. They are fully equipped for teaching the entire Medical curriculum both for University Degrees and the Conjoint Course.

The new West Wing of the Hospital is fully occupied; the rebuilding of the remainder is proceeding without the loss of a single bed; the remodelled Out-patient Department continues to expand; the newly built Residents' Block affords greatly improved facilities; the Nurses' Home is the finest in London. These, with other new buildings, including magnificent Laboratories, give to the Middlesex Hospital and its Medical School the most modern facilities obtainable in Great Britain.

THIRTY-ONE RESIDENT APPOINTMENTS are offered annually to students recently qualified. In addition, TEN REGISTRARS are also appointed annually.

SCHOLARSHIPS AND PRIZES of a value exceeding £1,000 are awarded each year.

Large Athletic Grounds at North Wembley.

There is no accommodation for women students.

City of Birmingham.
SELLY OAK HOSPITAL.

CASUALTY OFFICER (Male.)

Applications are invited from fully qualified Medical Practitioners for the whole-time appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical and Children's Disease sections. There are completely equipped Pathological and Biochemical Laboratories and X-ray, Electro-therapeutic, Massage, Ultra-violet Ray and Electro-cardiographic Departments. Over 3,000 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time for a further period of not exceeding six months.

The person appointed will be required to assist at operations, to administer anæsthetics, and to undertake casualty and such other duties as may be assigned to him by the Medical Superintendent.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance). The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars of the appointment may be obtained from the Medical Superintendent, R. P. STANLEY KELMAN, Esq., M.B., Ch.B., F.R.C.S. (Eng. & Edin.), at the Selly Oak Hospital, to whom applications, stating age, experience and qualifications, accompanied by copies of recent testimonials, should be forwarded not later than Wednesday, July 15th.

The Council House, Birmingham. F. H. C. WILTSHIRE, Town Clerk.

June, 1931.

City and County of Kingston-UPON-HULL.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation of Kingston-upon-Hull invite applications for the position of Medical Officer of Health of the City at a salary of £1,500 per annum, rising by annual increments of £50 to £1,750 per annum.

The gentleman appointed will be required to act as School Medical Officer for the City, and Port Medical Officer and Medical Inspector of Aliens for the Hull and Goole Port Sanitary Authority. He will be required to devote his whole time to the duties of the office to which he is appointed and will not be allowed to engage in private practice, and all emoluments out of public monies which may be payable to or received by him will have to be paid to the Corporation. He will be required to reside in the City and to contribute to the Corporation's Superannuation Fund.

Particulars of duties and a form on which applications should be made may be obtained from the Town Clerk.

Applications endorsed "Medical Officer of Health," addressed to the Town Clerk, Guildhall, Hull, must be delivered at the Town Clerk's Office, Hull, not later than Friday, July 17th.

Guildhall, Hull, J. R. HOWARD ROBERTS, Town Clerk.

June 29th, 1931.

Borough of Luton.
ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

The Luton Borough Council invite applications for the appointment of ASSISTANT MEDICAL OFFICER OF HEALTH and ASSISTANT SCHOOL MEDICAL OFFICER. The scale of salary for the appointment is at the rate of £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, but the commencing salary will be determined according to the experience of the selected candidate. There is no Superannuation Scheme.

The gentleman appointed will be required to devote the whole of his time to the duties, and to act under the directions of the Medical Officer of Health.

On receipt of stamped and addressed envelope, the undersigned will supply particulars of the appointment and application form.

Applications (on such form) accompanied by copies of not more than three recent testimonials, endorsed "Assistant Medical Officer of Health," must be delivered to me not later than Wednesday, July 22nd.

Canvassing is prohibited and will disqualify.

2, Upper George Street, Luton. W. SMITH, Town Clerk.

July 4th, 1931.

City of Manchester.
PUBLIC HEALTH DEPARTMENT.

CRUMPSALL HOSPITAL AND INSTITUTION.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Assistant Medical Officer at the Crumpsall Hospital (1,300 beds) and Institution (1,600 beds), including 600 beds for Mental patients—Crescent Road, Crumpsall, Manchester.

Every applicant must be a registered Medical Practitioner, and unmarried

Preference will be given to applicants with previous Hospital experience

The Hospital is a recognised Training School for Nurses, and is equipped with all modern hospital requirements

Salary £275 per annum, with board, residence, and laundry in addition No bonus

The appointment will be made, in the first instance, for a period of six months The successful candidate, however, will be eligible for re appointment for a further period of six months at the end of that period

July 6th, 1931.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1931. Applications should reach the War Office not later than July 20th, 1931.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1931, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—From £488 to £2,000 a year according to rank and length of service.

Candidates who have held a full-time house appointment in a recognised civil hospital before appointment to a permanent Commission in the R.A.M.C. may, subject to certain conditions, be allowed to count the period of service in such an appointment, up to a maximum of 12 months, as Army service for promotion and increase of pay.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £364 10s. per annum normally earned by a Major after 20 years' service, to £920 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I.), Whitehall, London, S.W.1.

County Council of Middlesex.

OPHTHALMIC SURGEON.

The County Council invites applications for the appointment of Ophthalmic Surgeon (part time) for work at Ophthalmic Clinics established by the County Council at Uxbridge, Feltham, and Teddington, for the treatment of visual defects and diseases of the eye occurring amongst children attending schools under the control of the County Council, and women and children residing in the County Council's area for Maternity and Child Welfare purposes

The possession by applicants of the F.R.C.S. or D.O.M.S. Diploma will be an additional recommendation

The person appointed will be required to attend for one session (of about two hours) per week during the school terms at each of the above-mentioned Ophthalmic Clinics. Remuneration will be at the rate of £2 12s. 6d. per session.

Applications, stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than July 18th.

No special application forms are provided. Envelopes must be endorsed "Ophthalmic Surgeon." Canvassing, directly or indirectly, will be a disqualification.

Guildhall, Westminster, S.W.1. June 26th, 1931. ERNEST S. W. HART, Clerk of the County Council.

City of Leeds.

SENIOR ASSISTANT RESIDENT MEDICAL OFFICER KILLINGBECK SANATORIUM.

Applications are invited from registered Medical Practitioners for the post of Senior Assistant Resident Medical Officer at the Tuberculosis Sanatorium, Killingbeck (220 beds).

Applicants must be unmarried, and preference will be given to those who have held a General Hospital appointment and had experience in the treatment of Pulmonary and Surgical Tuberculosis in sanatoria. The salary offered is £350 per annum, rising by annual increments of £25 to £450, together with board, residence, and laundry.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund, established under the Local Government and Other Officers Superannuation Act 1922.

Form of application may be obtained from the Medical Officer of Health, 12, Market Buildings, Vicar Lane, Leeds. Applications, endorsed "Tuberculosis Officer" together with copies of three recent testimonials, should be delivered at my office, 26, Great George Street, Leeds, not later than 10 a.m. on Saturday, July 18th.

THOS. THORNTON, Town Clerk.

County Borough of Blackburn.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER

Applications are invited from registered Medical Practitioners for the post of Assistant Medical Officer (male), who will act under the supervision of the Medical Officer of Health and the School Medical Officer.

The person appointed must devote the whole of his time to the service of the Corporation.

The duties of the office will consist largely, but not exclusively, of work in the School Medical Department, and preference will be given to candidates with a Diploma in Public Health, and having experience in Infectious Diseases.

The salary will be £500 per annum to be increased by annual increments of £25 to a maximum of £700 per annum.

Forms of application, and further particulars of the duties and conditions of the appointment may be obtained from the Medical Officer of Health, Victoria Street, Blackburn.

Completed forms, accompanied by copies of three recent testimonials, must reach me by Saturday, July 25th, and should be endorsed on the envelope "Assistant Medical Officer."

Canvassing will disqualify.

Town Hall, Blackburn. July 2nd, 1931. BRIGGS H. MARSDEN, Town Clerk.

Hospital for Women at Leeds.

(For the Treatment of Diseases Peculiar to Women.)

HOUSE SURGEON wanted to commence duties on August 1st next. Salary £100 per annum, with board, quarters, and laundry.

Applications, together with copies of testimonials, should be sent to the undersigned immediately.

B. L. JEAFFRESON, Hon. Secretary to the Faculty.

Birmingham Public Health DEPARTMENT.

TUBERCULOSIS SECTION.

Applications are invited from single male Medical Practitioners for the post of ASSISTANT MEDICAL OFFICER in the Tuberculosis Section of the Public Health Department. The successful candidate will be employed both in a Sanatorium and a Dispensary.

Candidates should have held a resident General Hospital appointment, or an appointment in some Institution set apart for the treatment of those suffering from Tuberculosis.

The salary will be at the rate of £400 per annum, rising by annual increments of £25 to £450 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, and to the candidate passing a medical examination, and will be subject to one month's notice on either side.

Forms of application may be obtained from, and should be returned with three recent testimonials to, the Chief Clinical Tuberculosis Officer, 44a, Broad Street, Birmingham, by 9 o'clock on July 24th.

Council House, Birmingham. F. H. C. WILTSHIRE, Town Clerk.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as ASSISTANT MEDICAL OFFICER (full time) (man or woman) at the MAUDSLEY HOSPITAL, Denmark Hill, S.E.5, for Treatment of Incipient Mental Disorder. Candidates must be under 40 years of age (unless already in the Council's Mental Hospital Services), must be registered to practise both in Medicine and Surgery in England, and must have held a residential position in a General Hospital for six months, or have had comparable general experience.

Appointment pensionable under the Asylums Officers Superannuation Act, 1909. Salary £475 a year, rising to £550 a year (additional allowance of £50 to holders of D.P.M.). No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. In the case of a woman, marriage terminates contract of service.

Application form, giving full particulars, obtainable from Chief Officer (Ref. E), L.C.C., Mental Hospitals Department, Artillery House, Artillery Row, S.W.1.

Applications must be received by Friday, July 17th. Canvassing disqualifies.

MONTAGU H. COX, Clerk of the London County Council.

South London Hospital for WOMEN,

South Side, Clapham Common, S.W.4.

The Board of Management invite applications from fully qualified Medical Women for the undermentioned appointments:

Two HOUSE SURGEONS. Each for a period of six months from August 1st.

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St Pancras, in the County of London

·SPRAINS·

ARTICULAR and Muscular Sprains and their complications, such as swelling, tension in joints, rupture of muscles and tenderness, in addition to pain and loss of power, are best treated by absolute rest to the injured part, and by a hot application, which will retain its heat for hours.

Antiphlogistine

applied thickly and smoothly, promotes to a marked degree, the rapid absorption of extravasations. It checks or limits immediate bleeding, and prevents or diminishes secondary effusions.

A Symposium on Fractures

JUNE NUMBER—SURGICAL CLINICS OF NORTH AMERICA

Undoubtedly the outstanding feature of this number—from New York City—is the *Symposium on Fractures,* resulting from the Clinical Meeting of the New York Fracture Committee of the American College of Surgeons. Here are 14 clinics, each taking up a different fracture or a different phase of fracture work, and each presented out of wide experience. In addition, there are clinics on other subjects of daily clinical importance—such as gastro-intestinal surgery, liver and kidney work, bladder cases, hernias, pediatrics—39 clinics in all.

CONTENTS OF THE JUNE NUMBER

Clinical Meeting
New York Fracture Committee
American College of Surgeons
Conducted by Drs. Wm. Darrach and Clay R. Murray

Frederic W. Bancroft, *Fifth Avenue Hospital.*
Introduction to Symposium on Fractures.

Contribution by Dr. Charles L. Scudder, *Boston*
Opportunities for Contact with Recent Fracture Treatment

Clinic of Dr. William Darrach, *Presbyterian Hospital.*
Open Treatment of Fractures

Clinic of Dr. Royal Whitman, *Hospital for Ruptured and Crippled.*
Abduction Treatment of Fracture of Neck of Femur.

Clinic of Dr. Armitage Whitman, *Hospital for Ruptured and Crippled*
The Plaster-of-paris Spica as an Adjunct of the Abduction.

Clinic of Dr. Seth M. Milliken, *New York Post-Graduate*
Methods of Treatment in Various Forms of Fractures.

Clinic of Dr. Fenwick Beekman, *Hospital for Ruptured and Crippled.*
Care of Compound Fractures.

Clinic of Dr. Leo M. Davidoff, *Fifth Avenue Hospital.*
Fractured Skulls

Clinic of Dr. Walker E. Swift, *Beekman Street Hospital.*
The Pathology of Fractures of the Spine.

Clinic of Dr. Win H. Watters, *Beekman Street Hospital*
Treatment of Fractures of the Spine.

Clinic of Dr. Robert H. Kennedy, *Beekman Street Hospital.*
Emergency Treatment of Fractures.

Clinic of Dr. S. P. Bartley, *Long Island College Hospital*
Traumatic Separation of the Symphysis Pubis and Right and Left Sacro-Iliac Joints, Complicated by Internal Injury (Retroperitoneal Hemorrhage).
Treatment of Fractures of Body of Os Calcis; Demonstration of Technic (Open and Closed); End-Results.

Clinic of Dr. James Harry Heyl, *Beekman Street Hospital.*
Fracture of the Patella.

Clinic of Drs. Sigmund Mage and Thomas McGrain Lowry, *Beekman Street Hospital.*
Fractures of the Shaft of the Femur.

Clinic of Dr. Howard Lilienthal, *Mt Sinai Hospital.*
Diaphragmatic Hernia of the Liver.
Abscess of Lung, Interlobar Empyema. Death Necropsy.

Clinic of Dr. Winfield Scott Pugh, *City Hospital.*
Ruptures of the Kidney.
Massive Calculi in a Remaining Kidney.
Unilateral Renal Block by Calculus.

Clinic of Dr. Edward J. Donovan, *St Luke's Hospital*
Splenectomy for Thrombocytopenic Purpura.
Subtotal Gastrectomy for Penetrating Ulcer of the Lesser Curvature of the Stomach
Intestinal Obstruction Due to Carcinoma of the Sigmoid, Cecostomy, Mikulicz Operation Ten Days Later.

Clinic of Dr. Edward J. Donovan, *Babies' Hospital*
Transplantation of Ureters into Sigmoid for Exstrophy.
Congenital Hypertrophic Pyloric Stenosis.
Splenectomy in Eleven Months Child for Gaucher's Disease.
Repair of a Diaphragmatic Hernia in an Infant

Clinic of Dr. Frank M. Frankfeldt, *New York Polyclinic Hospital, Service of Dr F. C Yeomans*
Some Common Rectal Disorders—Newer Treatments.

Clinic of Dr. Benjamin N. Berg, *From the Surgical Service of Dr John F. Connors, Harlem Hospital*
Coexistence of Perforated and Bleeding Duodenal Ulcers.
Filarial Lymphatic Varices in Groin Resembling Hernias.

Clinic of Dr. William L. Sneed, *Hospital for Ruptured and Crippled*
Acute Infections of the Hip.

Clinic of Dr. Benjamin Rice Shore, *St. Luke's Hospital, Service of Dr. Walton Martin.*
Congenital Elevation of the Scapula.

Clinic of Dr. Guilford S. Dudley, *Bellevue Hospital*
Choledocholithiasis and Chronic Pancreatitis No Jaundice Common Duct Defect, Apparent Spontaneous Canalization. Chronic Ulcerative Colitis. Recto-sigmoid Stricture. Ileoproctostomy. Repair with Exclusion of Colon.
Carcinoma of Stomach

Clinic of Dr. William F. MacFee, *St. Luke's Hospital*
Endometriosis of the Abdominal Wall Case Report
Torsion of Pedunculated Fibromyoma of Uterus Producing an Intraperitoneal Hemorrhage Autotransfusion.

Clinic of Dr. J. William Hinton, *Bellevue Hospital.*
Marginal or Jejunal Ulcers.

Clinic of Drs. Joseph B. Stenbuck and James C. Whitaker, *From the Surgical Service of Harlem Hospital, Dr. John F Connors, Director.*
Empyema Thoracis, Gauze Packing of Pleural Cavity

The Surgical Clinics of North America. Issued serially, one octavo volume of about 275 pages, illustrated, every other month Per year (6 numbers) Cloth, 75s net, Paper, 55s net

These clinics are sold by a year of six numbers.

AN INDEX OF

DIFFERENTIAL DIAGNOSIS OF MAIN SYMPTOMS

By Twenty Representative Contributors.

Edited by

HERBERT FRENCH, C.V.O., C.B.E., M.A., M.D.Oxon., F.R.C.P.

Consulting Physician to Guy's Hospital.

This work is of practical utility to medical men whenever difficulty arises in deciding the precise cause of any particular symptom of which a patient may complain. It covers the whole ground of Medicine, Surgery, Gynaecology, Ophthalmology, Dermatology, and Neurology.

"Both authors and publishers deserve great praise for producing a volume which in substance brings the highest credit to British medicine, and in format holds its own with the most lavish of transatlantic productions."—BRITISH MEDICAL JOURNAL.

"The fund of knowledge contained in this volume is incalculable . . . admirably illustrated."—LANCET.

"Beyond question a *tour de force* . . . will be found a friend in need at all times."—PRACTITIONER.

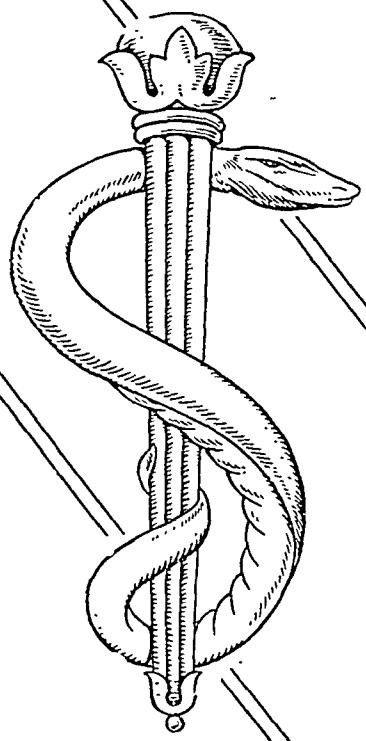
IMPORTANT ANNOUNCEMENT

A new range of Hanovia Lamps will be shown for the first time at the Exhibition at Eastbourne July 20th - - - 24th



These new models incorporate some very important changes. They set a new standard of value in the field of actino-therapy equipment, being easier to operate, better finished and of higher efficiency—thus achieving better therapeutic results.
All these models will be demonstrated at Stand No. 3 at this Exhibition.

If you cannot attend the Exhibition, send for our new free booklet "What is Modern Actinotherapy?" marking the enquiry Dept. 9.

SALTAIR SURGICAL SERVICE

Medical opinion of to-day pays great tribute to those, who—in the past, with crude appliances and knowledge—blazed the trail which has led to the high standard of Modern Surgical Science.

The House of Salt, since its establishment in 1793, has recognised that stock appliances could never adequately meet specialised Surgical requirements.

Salts have always acted in co-operation with the Medical Profession—making each appliance specially to individual requirements as prescribed by the attendant Practitioner.

London Consulting Rooms:
"OAKLEY HOUSE," 14-18, Bloomsbury Street, W.C.1.
Female Fitters in attendance Monday to Friday.
Orthopaedic Mechanician Wednesdays only.
By Appointment

DEAF DOCTORS

AND DEAF PATIENTS

HAVE proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "'Ardente' is a godsend to me"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, adjusted, and supplied.

RHEUMATOID and OSTEO-ARTHRITIS

Amidst the recognised difficulties in treatment of advanced cases of Rheumatoid and Osteo-Arthritis it is not generally realized that many patients have been restored to active life after being bedridden, suffering great pain for years, by Hoefftcke's Ambulatory Extension Treatment.

Many cases have been described by eminent medical men, some results of which are shown below.

FIG. 1.—December, 1921.

Case of Mrs. H., aet. 35.

FIG. 1.—Shows the knee-joint fixed in a position of partial flexion; patella ankylosed.

FIG. 2. — Shows after an interval of 9 years the improvement which resulted from 3 years' extension treatment—the complete restoration of the tibio-femoral joint which permits of free and painless flexion and extension.

This case was one of exceptional severity. In the average case the Extension Walking Appliance can be discarded in one or two years from the time of its first application.

FIG. 2.—April, 1930.

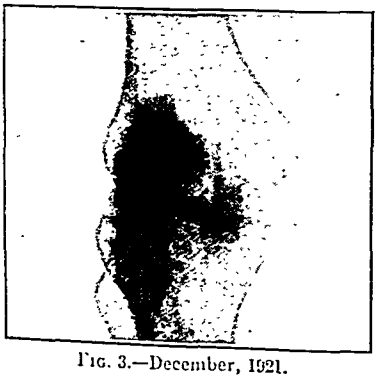

FIG. 3.—December, 1921.

FIG. 3.—Shows the irregularity of the outline of the articular surfaces as seen from before backwards. The interval between the bones is practically obliterated.

FIG. 4.—Shows the joint in an antero-posterior plane. Note the restoration of the outlines of the articular surfaces and the formation of a practically normal interval between the bones.

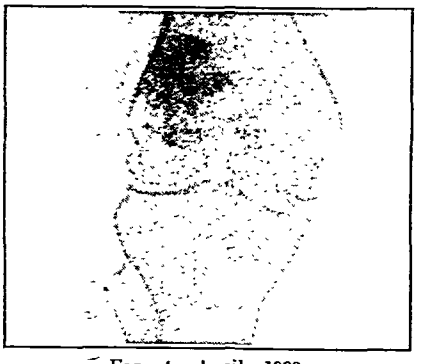

FIG. 4.—April, 1930.

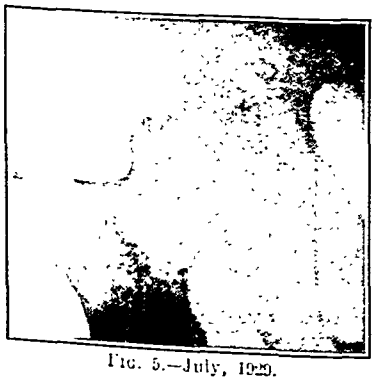

FIG. 5.—July, 1929.

Case of Mr. S., aet. 63.

FIG. 5.—Shows the hip-joint practically ankylosed in the adducted position. Patient hardly able to walk with great pain.

FIG. 6. — Shows spike absorbed; cavity filled in; head of femur covered with new cartilage, resulting in free abduction with full painless movement in the joint.

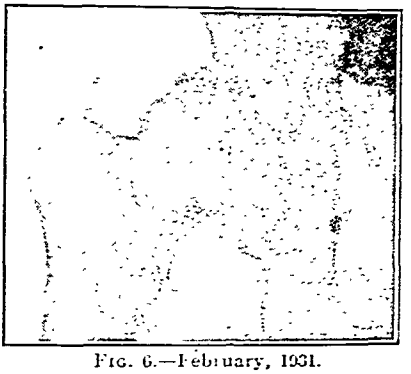

FIG. 6.—February, 1931.

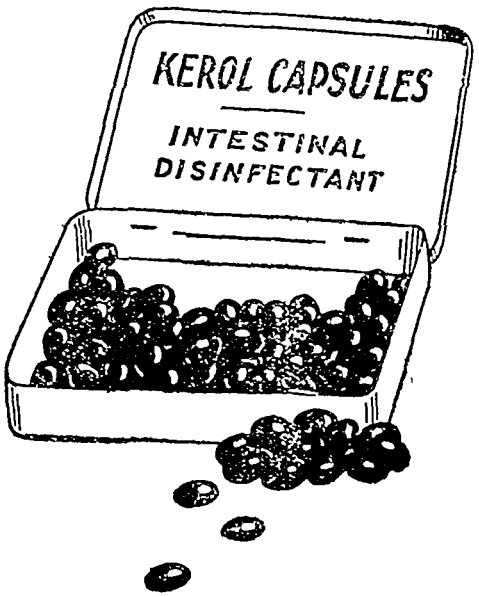
Original radiograms of these and other cases can be shown by appointment with

Mr. CAREL A. HOEFFTCKE, at 7, Harley Street, London, W.1,

on Tuesdays, Wednesdays, and Thursdays, or at BELLE VUE SPA, TREFRIW, NORTH WALES, any week-end, Friday to Monday.

ARTERIO-SCLEROSIS

IT is an old adage that a man is "as old as his arteries," meaning that degenerative changes in the arteries are largely responsible for senility.



The modern view is that arterio-sclerosis is produced by increased blood-pressure, and that increased blood-pressure results from the absorption of "pressor" substances developed by putrefactive bacteria in the intestine.

(Prof A Robin, among his suggestions for the treatment of arterio-sclerosis, emphasises in the first place the need to remove the alimentary toxic factors which are causative of arterial hypertension.—*Therapeutique Usella du Practicien*, p. 344.)

To retard the activity of the putrefactive bacteria, Metchnikoff introduced the soured milk treatment; but how much better it is to use an antiseptic substance. The ordinary so-called intestinal antiseptics, such as Salol, possess little real disinfectant power, and more potent germicides, such as Phenol, are absorbed, and, in sufficient dose, are toxic.

The active principle of Kerol, besides being a very potent germicide, is not absorbed, and is therefore non-toxic. The rational treatment of arterio-sclerosis would, therefore, include adequate intestinal disinfection by means of the keratin-coated Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated): they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Kerol Capsules

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Feen-a-mint

REGD TRADE MARK

The Chewing Laxative

Peristaltic Promotion

Feen-a-mint definitely promotes peristalsis without griping, and without irritation to the intestinal or reno-vesical mucosa. Its marked activity is due to the minute state of sub-division of its active principle (phenolphthalein) which is incorporated into a resinous gum base. Mastication assists further its division—thus a maximum therapeutic effect is exhibited.

Definite Defaecation

Feen-a-mint is valuable at all ages. It is a beneficial aid in 'difficult' and intractable cases—especially those due to habit-forming drugs, pregnancy, neglect and post-operative stasis. It has no secondary effects, and is not incompatible with any concurrent treatment. Pleasant to take, bland, yet certain in result, and non-habit-forming, Feen-a-mint is free from all objection to the patient.

Feen-a-mint is of marked assistance in

THE NATURAL MINERAL WATERS
OF
CARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

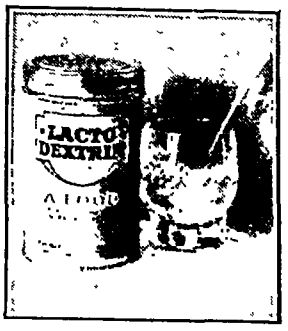
These waters act:

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of
Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:



INGRAM & ROYLE, Ltd.,
BANGOR WHARF, 45, BELVEDERE ROAD. LONDON, S.E.1.
And at LIVERPOOL and BRISTOL.
Samples and Descriptive Pamphlet forwarded on application.

FAVOURABLE REPORTS *in clinical use of this combination of Lactose and Dextrin*

FURTHER reports have recently been received giving testimony to the value of Lacto-Dextrin as a food for changing the intestinal flora. Lacto-Dextrin is highly efficient in promoting the growth and development of both B. acidophilus and B. bifidus in the colon.

Another important laxative agent for use in conjunction with Lacto-Dextrin is Battle Creek Psylla (psyllium seed). This emollient evacuant supplies both bulk and lubrication and is of special service in fissure and haemorrhoids.

Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, Ltd., 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

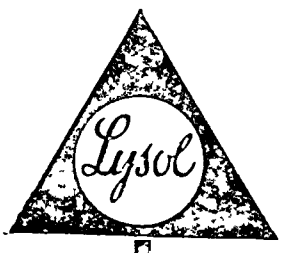
LACTO-DEXTRIN



Products of the BATTLE CREEK FOOD CO., Mich., U.S.A.

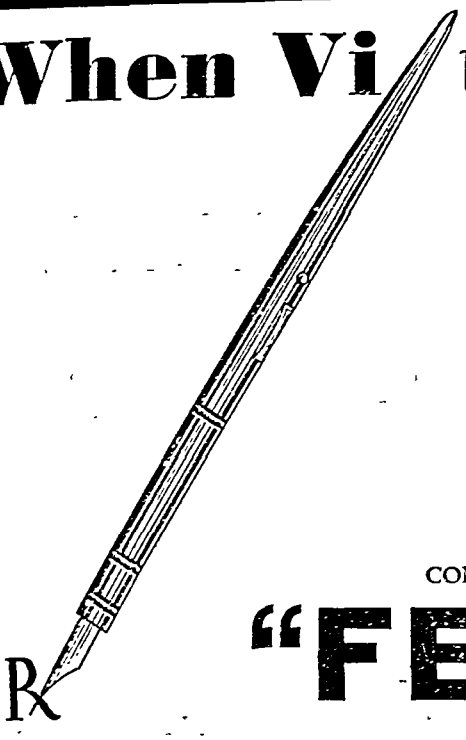
THE ONLY LYSOL MADE TO THE ORIGINAL FORMULA. MARSHALL'S is relied upon by the greatest hospitals throughout the world. For your next case specify— MARSHALL'S LYSOL.

Sample free on request to members of the medical and nursing professions

LYSOL LTD., Dept. K 19b, RAYNES PARK, S.W.20.

THIS IS YOUR SAFEGUARD

The name MARSHALL'S on a Lysol bottle is an assurance that the doctor and nurse can place implicit confidence in its germicidal and antiseptic efficiency.



There are cheaper Lysols than MARSHALL'S, but the standard of quality set by the original product has never been equalled. There are preparations claimed to be "just as good," but MARSHALL'S LYSOL can be relied upon in every type of case as no other preparation on the market to-day. Its emollient action makes it safe to use for the most delicate purposes, and in the correct dilution it will not roughen the hands or corrode instruments.

The germicidal activity of MARSHALL'S Lysol is not impaired by the presence of organic matter, so it is efficient under all conditions.

MARSHALL'S *Lysol*

toyds

When Vitality is Low

Demineralization causes many cases of cachexia, debility, undernutrition, neurasthenia, anemia and other run-down conditions. Remineralization is the remedy.

The ingredients of Compound Syrup of Hypophosphites "Fellows" are sodium, potassium, calcium, iron and manganese, together with phosphorus, quinine and strychnine.

Dose: 1 teaspoonful t. i. d.

COMPOUND SYRUP OF HYPOPHOSPHITES

"FELLOWS"

(Trade-Mark)

It supplies the needed minerals

TRADE "HEPATAGEN" MARK

(MIST. HEPATICA CONC. HEWLETT).

COMPOSITION—Ext. Cascaræ, Ext. Rhei, Jalapin, Podophyllin, Cocainæ Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

THIS excellent compound, first introduced as a general aperient and cholagogue, has now become a popular remedy in that class of cases spoken of as Chronic Biliousness, in Catarrhal Jaundice and in the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver, so frequently met with, it has been used with marked benefit.

In the treatment of acute or temporary constipation, frequently met with in the convalescence from acute disease and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

Packed only in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.
Price in England, 12/6 per lb.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

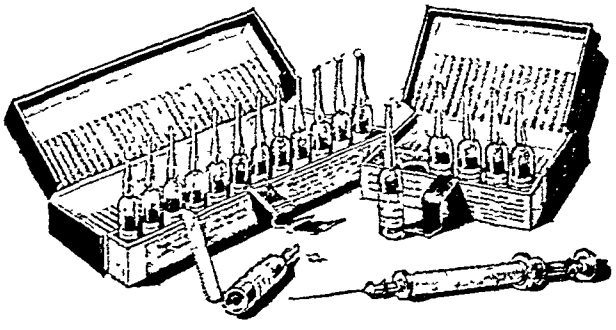
OVER 900 BRANCHES IN GREAT BRITAIN



The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD
Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Bismuth Treatment in Syphilis

It has been definitely established as a result of ten years' clinical experience in the use of Bismuth for the treatment of syphilis that the intramuscular injection of an aqueous suspension of a sparingly-soluble salt produces the most satisfactory results.

Bisoxyl is an aqueous suspension of Bismuth oxychloride in a very fine state of sub-division. In this condition the bismuth is absorbed slowly and regularly; hence Bisoxyl injections are practically painless and, at the same time, therapeutically effective.

A LARYNGEAL NARCOTIC

Prepared by a new process which enables SOLID BROMOFORM to be combined with CODEINE

IN TUBES OF TWENTY TABLETS

CONTINENTAL LABORATORIES LTD
30, Marsham Street, LONDON, S.W.1
"Tensilely Secret, London" Victoria 2041

TABLETS "B.S.C."

(Bile Salt Compound)

TRADE MARK

For Constipation, Intestinal Toxæmia, Hepatic Deficiency, Gall Stones and allied conditions.

Tablets "B.S.C." contain active pancreatic extract and bile acids, extract of duodenal mucous membrane and a proportion of ipecacuanha and emodin. Their administration stimulates the flow of glandular secretions which complete the digestive processes; the bile salts emulsify and detoxicate the food residue, while the emodin and ipecacuanha exert a tonic effect on the visceral musculature, particularly the colon, thus stimulating peristalsis.

Tablets "B. S. C." are of particular value in the treatment of constipation, hepatic disorders and the toxæmias arising from stasis. In conjunction with hexamine, they are of distinct benefit in the treatment of gall-stones and cholecystitis.

Supplied in bottles containing 40, 80, 160 and 500 at 2/6, 4/6, 8/6 and 20/-

Allen & Hanburys Ltd.
LONDON, E.2

Telephone: 3201 Bishopsgate (10 lines)

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of *hyperchlorhydria, gastric ulcer, fermentative dyspepsias* with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists, 184, Queen's Gate, London, S.W.7.

Works: KING'S LANGLEY, HERTFORDSHIRE. M231

ALOCOL

Colloidal Hydroxide of Aluminium

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

SUGAR

NUSALIN
(S. & M.)

"THE PERFECTLY BALANCED SALINE"

FREE

NUSALIN

A DISTINCTIVE EFFERVESCENT SALINE

For the correction of functional disorders of the Stomach and Intestines.

Mild but definite in action.

Easily controlled by dosage.

Provides the essential stimulus to organ function so frequently lacking when regular exercise is curtailed. Regulates the elimination of waste matter from the intestines.

Nusalin sets a high standard in Salines, being the nearest approach to Pharmaceutical Perfection, in its conception. It carries the personal recommendation of many Medical Practitioners.

NUSALIN

A SALINE OF EXCEPTIONAL PURITY

For the diabetic patient—Sugar Free.

For the Adult—A safe and effective corrective.

For the Growing—Removes toxic elements in the blood stream.

For the Child—Contains nothing drastic in action.

Free Literature will be forwarded to Members of the Profession on request.

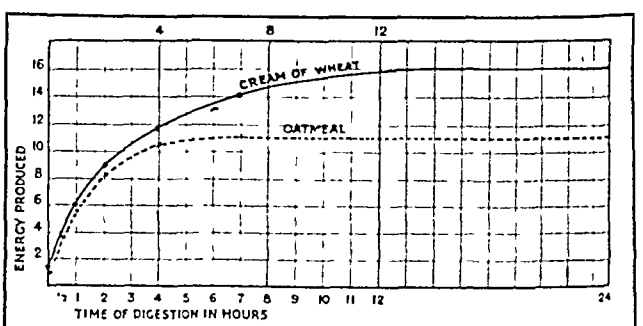
50% higher sugar yield

"After four hours the digestion of Oatmeal was at a standstill, while that of 'Cream of Wheat' continued for a further four"

THE paramount importance of starch in infant feeding, even as early as the 3rd month, is universally recognised to-day

Four outstanding advantages of its introduction are acknowledged to be



Slower carbohydrate digestion.
Prevention of fermentative diarrhoea.
Thorough metabolization of fat.
Retarded curd formation.

The results given opposite of experiments with "Cream of Wheat" by a leading Biochemical Institute are therefore of unique interest The general consensus of opinion in favour of a wheat cereal, compared with oats, makes them doubly so

Leading pediatrists put "Cream of Wheat" on their diet sheets both as a first solid food for infants and for children suffering from fat intolerance.

It consists entirely of the granulated endosperm of the best hard wheat and contains no harsh parts.

On receipt of a professional card full details of the above tests and a sample of "Cream of Wheat" will be sent. Dept W7 Fassett & Johnson Limited, 86, Clerkenwell Road London E.C.1

Replica of graph showing Diastatic Digestion of "Cream of Wheat."

1. The starches of "Cream of Wheat" were more rapidly converted into sugar.
2. After 4 hours the digestion of oatmeal was practically at a standstill while digestion of "Cream of Wheat" continued at a scarcely diminished rate for a further 4 hours or so.
3. When digestion was complete the amount of sugar from "Cream of Wheat" was nearly half as much again as that obtained from oatmeal.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in ford's Fluid Magnesia a reliable and safe which may be freely used for many and we would request your kind consof its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

AN INTERESTING COMPARISON

SOYOLK

FOR BUILDING

BONE — MUSCLE — NERVE

Soyolk is a highly digestible and pleasantly flavoured flour prepared from the Soya Bean, and is used largely in some of the leading hospitals and sanatoria. The nutritive value of this STARCH-FREE product is shown in the following comparative analysis.

	WATER	PROTEIN	FAT	CARBOHYDRATES	ASH	CALORIES
	%	%	%	%	%	per lb.
SOYOLK	9	42	20	25 (No Starch)	4	2165
FINEST WHEATEN FLOUR	13	12	1½	73 (70% Starch)	½	1750

SOYOLK FINEST WHEATEN FLOUR

The inclusion of Soyolk in some of the common farinaceous foods such as bread, confectionery, puddings, porridge, etc., adds substantially to their nutritional value and converts a merely carbohydrated food into a perfectly balanced article of diet.

Apply for free sample and literature to:

THE SOYA FLOUR MANUFACTURING CO., 7, MINCING LANE, E.C.3.

BISMULAIT

(DUNCAN)

A uniform and palatable preparation of Bismuth, containing 5 grains of freshly precipitated oxycarbonate of Bismuth in each fluid drachm. It is readily diffusible and the Bismuth is presented in the minutest hydro-amorphous condition. Bismulait is of the utmost value as a sedative or antacid in gastro-intestinal troubles.

Also the following Combinations:

BISMULAIT c PEPSIN.

Contains 2 grains of Pepsin in each fluid drachm. An ideal preparation for the treatment of Dyspepsia.

BISMULAIT c SALOL.

Contains 5 grains of Salol in each fluid drachm. For the treatment of Dyspepsia associated with fermentation.

Packed in 4 oz., 8 oz., and 16 oz. bottles.

Sample on application.

Remarks
ON
SOME CLINICAL PICTURES ATTRIBUTABLE TO LEAD POISONING
WITH SPECIAL REFERENCE TO THE NEUROLOGICAL MANIFESTATIONS OF PLUMBISM*

BY

EDWIN BRAMWELL, M.D., F.R.C.P.

MONCRIEFF-ARNOTT PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH; PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH

Perhaps it may seem strange that I should have chosen as the subject of this lecture a disorder which is relatively uncommon, and which may be said to be upon the wane. An explanation to justify my choice would consequently seem necessary, although I feel that no apology is called for. Lead poisoning may be acquired from numerous unsuspected sources, and may appear under a variety of subtle guises. The diagnosis (and it is of diagnosis that I propose particularly to speak) may be at once suggested by the patient's occupation, for there are certain industries in which it is common knowledge that the workers are especially exposed. On the other hand, there are many occupations in which the risk is not so generally realized and many different ways by which accidental lead poisoning may be brought about. When the preliminary anamnesis fails to indicate the cause the possibility of lead poisoning will not occur to the practitioner unless it is suggested by the symptomatic features which the case presents. Hence the importance of an acquaintance with the varied symptomatology of plumbism. The clinical pictures which I purpose to portray may consequently prove helpful.

My first consultation after entering practice some thirty years ago (the case was one of lead poisoning) has for various reasons left an indelible impression on my mind. Such memories are invaluable; they constitute, indeed, an essential part of clinical experience, for, when the exceptional and unexpected are again encountered, they may indicate the line of approach or even serve to determine the diagnosis. For the purpose of this lecture I have, with undoubted benefit to myself, and I trust the result may be not unprofitable to you, reviewed my experience of lead poisoning and selected from my notes of some thirty cases, in a number of which the cause had not been previously suspected, several which exemplify some of the diverse manifestations of plumbism and raise certain problems of interest in this connexion.

OCCUPATIONAL AND ACCIDENTAL LEAD POISONING

Since the recognition of the source of poisoning plays so prominent a part in diagnosis it may be well in passing that I indicate some of the industries fraught with special danger and some of the sources of accidental poisoning. Occupational lead poisoning has long been recognized, and periodic inspection of the employees engaged in many industries is now insisted upon as a routine procedure. Medical practitioners are, indeed, under a statutory obligation to notify cases of lead poisoning occurring in a factory or workshop. A great deal of valuable information has been so acquired, and the risks of industrial poisoning, which are now known to be largely due to the inhalation of particles of lead contained in dust or in fumes, have been materially diminished by the application of appropriate preventive measures. Sir Thomas Legge,[1] in a recent paper on industrial lead poisoning, has classified the cases of plumbism reported to him over a period of twenty-five years in his official capacity as the senior inspector of factories. The various occupations, including that of house painting, with the number of cases reported during the year 1925, were as follows: house painting, 88; electrical accumulators, 73; pottery, 45; ship breaking, 31; coach building, 23; smelting of metals, 22; ship building, 13; white lead, 12; enamelling, 9; printing, 8; paints and colours, 8; plumbing and soldering, 7; red lead, 7; tinning, 4; litho transfer making, 2; indiarubber, 2; other contact with molten lead, 17; paint used in other industries, 14; other industries, 29. There has been, it seems, a material and progressive diminution in the number of cases in all the occupations in which lead poisoning is specially met with, apart from electrical accumulators, a rapidly growing industry, and ship breaking, a new industry which came into existence during the war.

The term "accidental" is applied to cases of lead poisoning attributable to causes other than occupational exposure. These are very numerous, and often obscure. Contamination of drinking water derived from a peaty soil is, because of its comparative frequency, of special importance as a cause of chronic lead poisoning. The acids in the soft water act upon lead pipes, particularly if the pipes are new, and dissolve the lead. Instances are recorded in which epidemics of lead poisoning have been so produced. Poisoning may result when the quantity of lead in the water is not more than 0.01 grain per gallon. But it is not necessary that the lead should be in solution, for Sir Thomas Oliver[2] reports a case in which lead poisoning was caused by several lumps of white lead left in a cistern by careless workmen. The water was muddy in appearance from the precipitated lead, and lead was deposited on vegetables boiled in it. Among many other possible causes of accidental lead poisoning are the following: drinking aerated water from siphons with lead or pewter valves; drinking beer, wine, or cider which has been drawn through lead pipes; eating tinned articles of diet in which solder has been used in the tinning process; eating confectionery in the preparation of which lead chromate has been utilized for colouring purposes; drinking tea or eating food or sweets wrapped in lead foil, etc. Sucking the fingers and biting the nails after contact with white lead paint was the cause of the epidemic of lead poisoning in children reported by Lockhart Gibson[3] of Brisbane in 1897.

Although poisoning is very rarely caused by lead when prescribed for medicinal purposes, it is sometimes so produced. Plumbism has, for example, been reported in cases in which lead acetate has been given to control diarrhoea. Infants have been poisoned by lead ointment applied to an excoriated nipple. Poisoning has also been observed in cases in which an ulcer has been dressed with lead lotion. The risk of absorption of lead through the unbroken skin is very small, but lead poisoning has been known to follow the application of hair dyes, cosmetics, and lotions.

Lead has seldom been employed with criminal intent for purposes of suicide or homicide; at one time, however, it was widely used, and is still sometimes employed, as an abortifacient. Nowadays the sale of diachylon is restricted under the Poisons Act.

A CASE OF "LEAD NEURITIS" IN WHICH WEAKNESS OF THE RIGHT HAND WAS THE PATIENT'S SOLE COMPLAINT

The first case to which I shall direct your attention is in many respects typical, since it exemplifies the form of nervous lesion most often met with in lead poisoning.

A lead smelter, aged 34, was seen on January 8th, when he brought with him a note from his medical attendant to the effect that he had a right-sided radial paralysis. The patient stated that he had worked as a lead smelter for ten years,

* A British Medical Association Lecture delivered to the Leeds Division, March 25th.

that to his knowledge he had never had any symptoms of lead poisoning, and that he had had no illness prior to the onset of his present trouble some three months previously. At that time, when feeling otherwise perfectly well, he noticed that he was unable to straighten the middle and ring fingers of his right hand. The weakness of the hand, which had come on gradually and without apparent cause, had, he said, been progressive. Although he had had some sharp pains at times, extending from the region of the right elbow to the dorsum of the thumb, he had noticed no numbness or other subjective sensation in the skin. Further, it was ascertained from the patient, only, however, in answer to direct leading questions, that for the previous two months he had been rather constipated, that his appetite had been poor, and that occasionally he had had some pain in the lower abdomen, though this had never been severe, and from his description had not been definitely colicky in character. Again, he stated that there was no weakness of the left hand, and that he had been doing a full day's work up to the previous day.

Upon examination the patient's appearance was that of a healthy man, though he was possibly slightly anaemic. There was, indeed, a secondary anaemia, for the red cells numbered 3,610,000, the haemoglobin was reduced to 55 per cent., and there was a distinct punctate basophilia. The extensors of the right hand, notably those of the middle and ring fingers, of the thumb, and of the wrist, were obviously weak, though there was no definite wasting; there was no paresis of the small muscles of the hand, of the brachio-radialis, or of other muscles of the arm. The muscles of the right forearm and upper arm were hypersensitive on pressure. The deep reflexes of the right arm were less active than those on the left side. There was no sensory loss. Despite the patient's statement that he had noticed no weakness of the left hand, the power of the extensors of the left wrist, but not that of the fingers, was found to be definitely reduced when tested against resistance. There was no weakness of, or alteration in, the reflexes in the lower extremities, and no tremor, nor was there a blue line on the gums, but it should be added that the patient was edentulous. Further examination revealed no additional physical signs. Lead was not found in the urine even after large doses of potassium iodide had been given for three days.

There can, you will agree, be no doubt as to the diagnosis of lead poisoning on the data I have presented to you. The patient's occupation, the bilateral though asymmetrical weakness of the extensors, the history of constipation, loss of appetite and abdominal pain, and the associated secondary anaemia with punctate basophilia place the diagnosis beyond question. But had it not been that the patient was a lead smelter, the possibility of lead might never have suggested itself, and the case might have been diagnosed on cursory examination as a simple radial palsy of undetermined etiology, for the patient's one complaint was of weakness of the right hand, he did not look ill, and it was only in answer to direct questions that the history of constipation and slight abdominal pain was elicited. There is indeed no reason why a lead worker should not develop a coincidental radial palsy. On the other hand, the gradual onset of the paresis affecting, in the first instance, the extensors of two fingers only, and the progressive course would probably, I think, have aroused the suspicions of those of you who have had some experience of lead poisoning.

A number of pertinent questions are raised by the case to which I have just referred. Why should a lead smelter develop symptoms of lead poisoning for the first time after working at his occupation for ten years? Sometimes, in similar circumstances, a history may be obtained to the effect that the patient had had influenza or some preceding illness, that he had been indulging in alcohol to excess, that he had been doing extra work, or that he had been especially exposed to lead immediately prior to the onset of his trouble. But in other cases, as in the present instance, no clear evidence of a determining cause is obtained. Then this case demonstrates a point I wish especially to emphasize—that wrist-drop due to a "lead neuritis" may be the first and only obvious manifestation of lead poisoning. Why should this be? The problem is an interesting one, since it raises the whole question of the selective action of poisons. Is it not an interesting fact that the musculature of the upper limbs, and particularly the extensors of the wrists and fingers, should be picked out so often by lead, whereas the lower limbs so rarely suffer? I know of no form of multiple neuritis, apart from occasional post-diphtheritic types, in which this is so. The study of the exceptional sometimes throws light upon the commonplace. Numerous reported observations appear to indicate that muscular effort plays a part in determining the incidence of the paralysis. The facts in this case are suggestive in this connexion, for the patient, whose work chiefly consisted in ladling lead, informed us that he was in the habit of grasping the end of the iron ladle with his right hand while he supported the shaft of the ladle with his left. The employees in the works in which this patient was engaged were, he informed us, inspected once a month, when the inspector examined the gums for the presence of the blue line, looked at the eyes for anaemia, and noted whether there was any tremor of the hands. With the exception of a slight degree of anaemia, however, none of these phenomena were present here. On the other hand, this case demonstrates that a paresis of the extensors of the wrist and fingers may be the first noticeable manifestation of lead poisoning, and that unless this is pronounced it may cause little if any disability. Consequently it would seem to be advisable to test the power of the extensors of the wrists and fingers as a routine procedure. J. P. Leake[4] has devised a special instrument for this purpose, but an ordinary dynamometer, which I am in the habit of using for recording progress in cases of radial palsy, appears to be all that is required.

Etiological Considerations

The cause of lead palsy is still the subject of debate. For long the paralysis has been regarded as secondary to the histological changes which are met with in varying degree, in individual cases, in the peripheral nerves and spinal cord. Gowers[5] recognized two clinical types, in one of which the symptoms resembled peripheral neuritis, in the other, a progressive muscular atrophy of spinal origin. Messing[6] in 1913 described inflammatory changes in the muscles which were not, he thought, to be accounted for by interruption of the nerve fibres. Hyslop and Kraus[7] in 1923 were of opinion from their careful anatomical studies that lead palsy is due to a neuronitis which may affect any part of the neuro-muscular apparatus, while Aub[8] and his co-workers conclude that "in the light of more recent work on the chemistry of muscular activity and of lead within the body, it seems probable that the physiological lesion of lead palsy is in muscle."

Chronic Lead Poisoning Simulating Malignant Gastric Disease

The following case is of considerable interest from the diagnostic point of view:

A business man, aged 62, whose home was in the North of Scotland, was seen on August 31st, 1900. A history was obtained from the patient to the effect that he had been an exceptionally healthy man up to two years previously, when he had had influenza, since which time he had been troubled with occasional attacks of abdominal pain, not related to food, and unaccompanied by vomiting. In February, 1900, six months before we saw him, he had a second bout of influenza, and after this never seemed to regain his strength. For some months he had been rapidly losing weight; in the spring he weighed 11½ st., whereas he now weighed only 8 st. 5 lb. Further, he informed us that for six weeks or more his arms had been becoming progressively thinner and weaker, and that he had been much troubled with what he described as boring pains in the arms, especially about the shoulders.

The patient was sallow, rather anaemic, and somewhat emaciated. There was pronounced symmetrical wasting and weakness of the upper limbs. So weak were the deltoids that he could only raise his hands for two or three inches from his sides. The extensors at the elbow were relatively weaker than the flexors, the extensors of the wrists and fingers were definitely weaker than their opponents, and the brachio-radialis had, I see from my notes, escaped. An occasional fibrillary tremor was to be seen in the wasted muscles. There was no sensory loss, nor was there any weakness or wasting of the lower limbs. The knee-jerks were present, equal, and not exaggerated, and the plantar reflexes were definitely flexor. The spine showed no deformity, limitation of movement, or localized tenderness. No tumour was detected in the abdomen, the stomach did not appear to be dilated, the liver and spleen were not enlarged, nor was there any glandular enlargement. The radial arteries were slightly thickened and tortuous, the blood pressure was not high, the heart was not enlarged, and there was no albumin in the urine.

Such were the leading facts. What was the diagnosis? Malignant disease of the stomach or bowel had been suggested some months previously, a diagnosis which might naturally suggest itself in view of the patient's age, the abdominal pain, the constipation, and the loss of weight. At a later date, the pain in the arms and associated wasting and loss of power had been attributed to secondary growths involving the cervical nerve roots. This diagnosis now appeared to be very unlikely in view of the facts that, although the abdominal pains had been present for two years, no tumour could be felt, that no peristalsis was observed, and that there was no enlargement of the liver or glands. Further, it seemed very improbable that the condition of the arms was to be explained by secondary growths involving the nerve roots in the cervical region, for pain in the back had not been complained of, nor was there any evidence of disease of the bone or of implication of the spinal cord.

When the clinician is confronted by a complicated case, and when the most suggestive line of inquiry fails to lead up to a diagnosis, other lines of approach must be explored. Now in this case, setting aside for the moment the history of abdominal pain and the loss of weight, the striking feature was the more or less symmetrical wasting and weakness of, and pain in, the arms. These phenomena were certainly indicative of peripheral nerve involvement. But a symmetrical neuritis confined to the upper limbs is very rarely met with apart from lead. Might the facts of the case perhaps be so explained? This would account for the frequent attacks of abdominal pain. The suggestion appeared very feasible. True the atrophic palsy was not limited to the extensors of the wrists and fingers, but this is by no means always so in lead poisoning. The fact that the brachio-radialis muscles had escaped was in itself suggestive. But the patient had had a great deal of pain in the arms, and pronounced pain is an unusual feature in cases of lead palsy. It might be, however, that some additional etiological factor, possibly the influenza, would account for this. The patient lived in the Highlands, and was it not consequently possible that there might have been a contamination of a moorland water supply? These facts were indeed most suggestive. Was any further evidence available? The gums were next examined, and a blue line was observed opposite the two lower incisor teeth. Although the blue coloration of the gums was very faint—indeed, it would probably have passed unnoticed unless it had been specially looked for—its presence was sufficient, in association with the other features of the case, to practically clinch the diagnosis. Upon further inquiry the patient informed us that, although it was true that the water supply of his house came direct from the moor, the present system had been laid down some eight years previously. Two additional lines of inquiry were still open to us. The urine was examined by a skilled analytical chemist, who reported that he could find no trace of lead, but in his report he referred us to a recent authority who had examined the urine in fourteen cases of chronic plumbism and was only able to detect lead in two of these. On the other hand, on analysing the tap-water from the patient's house, he detected 0.12 grain of lead to the gallon of water. Conclusive proof of the diagnosis was afforded by the progressive improvement in the patient's condition after the correction of the faulty water supply. Among features of particular interest in this case were the great loss of weight and the unusual severity of the pains in the arms. No doubt the two attacks of influenza had, by lowering the patient's resistance, determined the symptoms.

Two methods are employed in arriving at a diagnosis: that is, the diagnosis may be based on the positive findings or arrived at by a process of exclusion. This patient was examined thirty years ago, and the diagnosis was suggested directly from the physical examination, was supported by the history, and confirmed by the detection of lead in the water supply and the rapid improvement after this had been corrected. Had the patient been seen to-day a number of diagnostic methods might have been employed for purposes of exclusion or confirmation which had not at that time been introduced—for example, the examination of the gastric contents for free acid, radiograms of the gastro-intestinal tract and of the spinal column, and the examination of the cerebro-spinal fluid and blood. But apart from the possible detection of a punctate basophilia, the occurrence of which in lead poisoning had not at that time been described, no additional evidence of a positive kind would have been obtained from these procedures.

ACCIDENTAL LEAD POISONING SIMULATING GASTRIC ULCER AND PROGRESSIVE MUSCULAR ATROPHY

Another case in which the source of the lead poisoning was the drinking water is of interest. The facts were as follows:

A married woman, aged 33, the wife of a gamekeeper, living in Inverness-shire, was seen on January 4th, 1915. The patient, I was informed, had suffered for some years from progressive muscular atrophy, and had been troubled from time to time with symptoms which had been attributed to a gastric ulcer, though she had never, so far as was known, vomited blood or passed blood by the bowel. The history was instructive. Bloodless since childhood, the patient stated that at the age of 19 she married and left her home in the South of Scotland to live in Inverness-shire. She had two healthy children, and had had no miscarriages. Some six years before I saw her, up to which time she said she had had no illness, the patient began to be troubled with attacks of abdominal pain, vomiting, and diarrhoea. About the same time she noticed that her hands, particularly the right hand, were shaky. These symptoms had continued to recur, although it was significant that when she left home to stay with her relatives in the Border country, as she did for a few weeks each year, her health always improved. A medical man whom she consulted sent her to see a distinguished surgeon, who, the patient said, agreed with the diagnosis, but was of opinion that operation was not called for. (It would be of interest to hear from surgeons of large experience whether they have ever met with, or operated upon, cases of lead poisoning sent to them with a diagnosis of gastric ulcer, intestinal obstruction, or appendicitis. I know personally of one case which was admitted directly to a surgical charge as a case of chronic appendicitis in which the symptoms were, I think, almost certainly to be explained by the lead poisoning from which the patient was suffering.) For some months before I saw her the patient had also been suffering from severe pains in the knees and elbows with, so she said, some swelling of the joints.

Upon examination there was a complete symmetrical paralysis, with very pronounced wasting of the extensors of the fingers and wrists. There was, too, great weakness and wasting of the small muscles of the hands. No fibrillary tremors were observed. The brachio-radialis and the muscles

of the upper arm and shoulder girdle had escaped. There was no sensory loss, nor was there any weakness or alteration in the reflexes of the lower limbs.

The distribution of the paralysis in association with the history was most suggestive of lead poisoning. There was no blue line on the gums, but the patient was edentulous. Upon further inquiry it was ascertained that a new water supply from a peaty well had been introduced into the patient's house a few months before she first commenced to suffer from the symptoms above described. Corroboration of the diagnosis was obtained when the tap-water was examined and found to contain 0.4 grain of lead to the gallon.

Among a number of interesting features presented by this case were the following: the occurrence of diarrhoea and vomiting in association with the abdominal pain; the improvement which occurred when the patient left home; the arthritic pains which are observed in some cases of lead poisoning; the great wasting and weakness of the small muscles of the hands in addition to the extensors; and the patient's statement that, although her husband and children looked pale, and had never felt well after the introduction of the new water supply, they had not suffered from colic or paralysis. Women are, it is affirmed, more susceptible to lead poisoning than are men.

So pronounced was the wasting of the hands and forearms in this case that I was very doubtful as to the ultimate recovery of the muscles, but when I examined the patient in January of this year she had completely regained the use of the hands and arms, and was looking in robust health.

LEAD ENCEPHALOPATHY, DUE TO DIACHYLON POISONING, SIMULATING BRAIN TUMOUR

Cases of lead encephalopathy are rarely met with nowadays. I can only recall two occasions upon which I have made this diagnosis.

A widow, aged 28, was admitted to hospital under my care on October 9th, 1929, when she complained of intense headache, vomiting, and double vision, which symptoms had troubled her for a month. The patient was somewhat confused and agitated, and when first seen it was not possible to obtain from her a very precise history of her illness.

Upon examination she was well developed, well nourished, but distinctly anaemic. There was a right internal strabismus, which the patient said had been present since early childhood. The pulse rate was rather fast (104), but there was no febrile disturbance. The retinal vessels were engorged, and the right optic disc definitely swollen. Otherwise the cranial nerves presented no abnormality, and there was no history of otorrhoea. There was no weakness, inco-ordination, or tremor in the upper limbs. A slight degree of ataxia was present in the lower limbs, but no distinct weakness. The knee-jerks and one ankle-jerk were absent, as were the abdominal reflexes. Both plantar reflexes were definitely flexor. There was no tenderness of the muscles on pressure. Apart from a soft mitral systolic murmur nothing abnormal was detected on examination of the thorax and abdomen. The radial arteries were not thickened, the blood pressure was not raised, and the urine contained no albumin. The result of the examination of the blood was as follows: Red blood cells, 3,650,000; haemoglobin, 50 per cent.; white blood cells, 12,800. Differential count: polymorphonuclears, 80 per cent.; small lymphocytes, 20 per cent.; basophils, 1 per cent.; no punctate basophilia. The Wassermann reaction was negative in both the blood and the cerebro-spinal fluid. The latter contained two cells per c.mm. There was no increase of protein, and the colloidal gold test was 0011000000. No lead was found in the urine, which was examined on two occasions by the Ganassini test. The Zondek-Aschheim test for pregnancy was negative.

The diagnosis of lead poisoning, which was at once suggested by the blue line on the gums, was confirmed by further inquiry, and by the subsequent history of the case. The patient was obviously agitated and worried, and upon questioning her directly she admitted that, after missing a menstrual period two months previously, she thought she might be pregnant, and had bought an ounce of diachylon and two pennyworth of aloes, which she had made into pills and taken during the first fortnight of September. Further, she said that the headache and vomiting commenced immediately after she began to take the pills. Three days after the patient's admission to hospital she developed hallucinations and delusions of sex, and commenced to have severe attacks of abdominal colic. She was not taking potassium iodide at the time, a point of some interest, for cases have been reported in which symptoms of acute lead poisoning were precipitated by potassium iodide, in some instances long after exposure to lead had ceased. Gradually the patient's symptoms passed off, and when she was discharged, on November 21st, she was practically well. When seen on January 17th, 1931, she said that she felt in perfect health; she had had no further headache, abdominal pain, or vomiting, the knee- and ankle-jerks were present, the fundus oculi was perfectly normal, and she was no longer anaemic.

Lead encephalopathy, which is characterized by such symptoms as headache, vomiting, papilloedema, passing on it may be to optic atrophy, hallucinations, mental depression or exaltation, dementia, tremor, paresis, and epileptiform seizures, is undoubtedly very uncommon. Sir Thomas Legge[1] met with this diagnosis in only 1.1 per cent. of the male and 2.1 per cent. of the female cases reported between the years 1920–24. Byrom Bramwell long ago insisted upon the importance of keeping this possibility in view in suspected cases of brain tumour. It is possible, indeed, that some of the reported cases of recovery from brain tumour are to be so explained. Mott[10] was of opinion that lead encephalopathy was of the nature of an encephalitis. Aub[11] and his collaborators take the view that the process is meningeal, basing their conclusions on the observations of (*a*) Hassin, who found a marked proliferative meningitis and relatively slight changes in the brain, of (*b*) various observers who have found increased pressure and an excess of lymphocytes in the cerebro-spinal fluid, and of (*c*) Camus, who produced excitability, "hallucinations," and convulsions just before death in dogs in which lead had been injected into the subarachnoid space by cistern puncture, whereas no symptoms followed when the lead was injected into the brain substance.

W. B. Ransom[12] drew attention in 1900 to the then very prevalent use of diachylon as an abortifacient, and suggested that something should be done to restrict the indiscriminate sale of the drug. Although diachylon is now included in Part I of the poisons schedule, the case to which I have referred shows that it may still be obtained and is still used for this purpose. Indeed, one should always bear in mind the possibility of lead poisoning when one is consulted by a woman of child-bearing age who complains of severe headache and vomiting, who is perhaps anaemic, and in whom there is a history of amenorrhoea. It is to be remembered that a single dose of diachylon may produce symptoms of poisoning, that these may persist for months, and that they may be aggravated by an intercurrent febrile illness.

SPASTIC PARAPLEGIA A CONSEQUENCE OF LEAD POISONING

Doubt was at one time expressed as to whether a pronounced spastic paraplegia is ever produced by lead. The following case is of interest in this connexion:

A gentleman, aged 56, was seen on July 18th, 1911, complaining of difficulty in walking, which had troubled him for three or four years. He had, he said, had no previous illness, apart from an attack of typhoid fever some twelve years previously. The history he gave me of his illness was

as follows. Four years before I saw him the patient had been troubled for some weeks with a pain about the right knee. At the same time, or soon after, he noticed some weakness of the hands and a tendency to drag the right foot when walking. The right leg became gradually stiffer, and soon after the left leg became similarly affected. He then began to have attacks of severe abdominal pain, vomiting, and constipation. His brother, who lived in the same house, commenced at the same time to be troubled with stiffness in the legs. After the weakness of the hands and attacks of abdominal pain had persisted for some six months the patient's medical man recognized that he was suffering from lead poisoning. He wrote me: "It was about this time that I suspected plumbism, and found that the patient had a blue line on his gums. The drinking water was analysed by Dr. Falconer King, who reported the presence of 0.15 grain of lead per gallon. Since then the water has been taken from a well free from lead contamination, and the patient has greatly improved in health and power of walking. He seemed always better away from home." According to the patient's statements, the attacks of abdominal pain disappeared at this time and have not recurred, the power of the hands was gradually regained, but the difficulty in walking has persisted.

Upon examination the patient had a good colour, and was well nourished. The only symptom of which he complained was difficulty in walking. His general health was, he said, excellent. The gait was very spastic, both lower limbs being affected to the same degree, though the patient was able to walk across the room with the aid of a stick. The muscles of the thighs and of the anterior tibial group were somewhat wasted. No fibrillary tremors were observed. The knee-jerks were exaggerated, and there was bilateral ankle-clonus and a bilateral extensor response. There was no sensory loss, and nothing abnormal was detected on examination of the upper limbs, cranial nerves, or other organs.

I heard nothing more of this patient until January of this year, when, in reply to my inquiries, he wrote:

"I am now 74 years of age, and there is little difference in my health. The loss of power has not extended to any other part of my body. This would seem to indicate that the disease has been stationary ever since I discontinued using the poisoned water. My brother, who also suffered from lead poisoning, died about two years ago, aged 70. He never recovered the use of his limbs. Latterly he had one or two shocks, and was bed-ridden for a while before his death."

That the patient had suffered from lead poisoning is clearly shown by the history of attacks of abdominal pain, the weakness of the hands, the presence of the blue line on the gums, the detection of lead in the water supply, and the improvement that occurred after the source of poisoning had been eliminated. There can be practically no doubt that the spastic condition of the lower limbs was due to the same cause, for the difficulty in walking developed at the same time and ceased to progress after the water supply was changed. It is interesting to note that the patient's brother was similarly affected.

J. J. Putnam,[13] so long ago as 1887, described some cases of spasticity of the lower limbs in which he demonstrated lead in the urine. Kinnier Wilson,[14] who in 1907 reported four cases of amyotrophy in men who, from the nature of their occupations, must have been exposed to lead, in each of which the onset was with double wrist-drop, while in three there was a certain amount of spasticity in the lower limbs, remarks, "One cannot but be struck with the progressive nature of the affection, which is so contrary to the ordinary forms of lead poisoning where cures are by no means uncommon." In the present case, however, the progress of the nervous symptoms appears to have been definitely arrested.

COMMENTARY

The cases I have referred to illustrate some of the varied clinical pictures attributable to lead poisoning. Is it not a remarkable fact, though it is an everyday experience, that the same disease-producing agent may affect individuals so differently? We see this constantly exemplified, and yet we are often quite unable to account for the incidence of symptoms, and have to content ourselves by attributing the special symptomatology the case presents to some peculiarity of the virus, to personal idiosyncrasy or individual predisposition, or to the presence of additional etiological factors which it is not always possible to demonstrate or assess. While the majority of patients suffering from lead poisoning no doubt come to the practitioner complaining of attacks of colicky pain referred to the lower abdomen associated with constipation, of cramps, of general debility, and of other symptoms associated with anaemia, these symptoms may, as exemplified by more than one of the cases to which I have referred, be relatively insignificant while the nervous phenomena predominate. When this is so, the nature of the condition, as I have emphasized, may never occur to the clinician, even when he happens to be conversant with the clinical features which may be met with as a consequence of lead. Personally I have a guilty feeling that I have probably failed to recognize cases of the kind. Sometimes, perhaps, because one has not realized the occupational risk, sometimes because one has not elicited the history with sufficient care, sometimes because the symptoms have suggested to one a different etiology, and sometimes because, although one has suspected lead, one has not been able to obtain confirmatory evidence.

When, in any given case, one suspects lead poisoning from the character of the nervous symptoms, what are the points to which special attention should be paid for purposes of corroboration?

1. The patient's occupation may raise the possibility. Reference has been made to those industries in which there is a special risk.

2. Upon inquiry one may obtain a characteristic or suggestive history of attacks of intermittent, colicky, lower abdominal pain which is relieved by pressure.

3. The blue line on the gums, when present, is distinctive. It is, however, merely an indication of exposure, and not necessarily of poisoning, for many lead workers show the blue line and manifest no symptoms. But when symptoms are present which raise the possibility of plumbism the blue line is of the greatest diagnostic value. It is, however, to be remembered that this sign fails us when the patient is edentulous or the teeth well cared for.

4. The examination of the blood in most cases of lead poisoning shows a secondary anaemia with, in almost all cases, a punctate basophilia, which may, however, vary from day to day. To the latter appearance much importance is attached as an indication of early lead poisoning. Although not pathognomonic (for an occasional cell showing punctate basophilia may, it is affirmed, be sometimes seen in normal blood, and cells of this type are also met with in pernicious anaemia and leukaemia), the presence of definite stippling is a most suggestive sign in a case of suspected plumbism.

5. Lead may be found in the urine, and its presence is then a clear indication that it has been absorbed into the system. On the other hand, its absence does not exclude lead poisoning, for the lead may be retained in the tissues. Of 200 patients with suspected lead poisoning examined at the Mayo Clinic[15] 100 were shown to be excreting lead in the urine. Lead may indeed be found in the urines of individuals who are admitted to hospital for various conditions, who have not encountered obvious occupational hazards, and who present no symptoms suggestive of lead poisoning. Consequently, while further observations are called for, the presence or absence of lead in the urine is a point to which too much importance must not be attached.

From what I have said you will see that, while in many cases the diagnosis of lead poisoning is obvious, in others the possibility may never suggest itself, while

even in cases in which one suspects lead as the cause of the clinical picture a definite conclusion may only be arrived at after a careful consideration of all the facts if the source of poisoning is not detected.

Coincidences are sometimes remarkable. Two days ago, within an hour of writing the above lines, I saw at the hospital a man, aged 50, who had been under my care in June of last year with an anterior crural neuritis of undetermined etiology. The patient has now practically recovered, but the symptoms, as the notes showed, were anomalous. I recalled a remark of that great clinical master Sir William Gowers,[16] who in writing of the diagnosis of lead poisoning says, "It is not possible to avoid error in such cases except by the habit of remembering lead as a possible cause in obscure cases." Was it possible that this man's symptoms had been caused by lead? Upon inquiry as to his occupation he informed me that he was a house painter, and, further, I found that while he was in hospital the house-physician had noted the presence of "a slight blue line round the gums." The teeth had since been extracted, and the line had consequently disappeared. Further, the patient stated that, although he had worked as a house painter for thirty-five years, he had never been troubled with abdominal pains, weakness in the hands, or, so far as he knew, any symptom of lead poisoning. The probabilities would, however, appear to be that this was the cause of his symptoms in view of their anomalous character and the absence of any other apparent etiological factor.

There is a natural tendency to associate symptom-complexes with individual diseases. Now while this is of undoubted value in furthering the general recognition of the disorders in question, it has its disadvantages. There can, for instance, be no question that the symptomatic triad—intention tremor, nystagmus, and scanning speech—emphasized by Charcot in disseminated sclerosis, was too restricted and retarded diagnosis in so far as it failed to include many cases which we now know to be due to the same pathological process. Similarly the three symptoms of lethargic encephalitis to which so much importance was originally attached—lethargy, febrile disturbance, and ocular palsies—concentrated attention upon one particular type of the disease. The same applies to the diagnosis of plumbism, for when we think of lead poisoning most of us, no doubt, at once recall the characteristic wrist-drop, whereas we are apt to forget that a variety of nervous symptoms may be so produced. There is an aphorism so familiar that it savours of a platitude—"More mistakes are made by not looking than by not knowing." Mistakes in the diagnosis of lead poisoning are often due to not expecting. My purpose will have been achieved if I have succeeded in impressing you with the importance of thinking of lead poisoning as a possibility in every case with which you meet which presents anomalous nervous symptoms.

CUMULATIVE EFFECTS OF INFINITESIMAL DOSES OF LEAD*

BY

NORMAN PORRITT, M.R.C.S., L.R.C.P.

CONSULTING SURGEON, HUDDERSFIELD ROYAL INFIRMARY

There are two types of plumbism: one, the classical lead poisoning of the textbooks, caused by massive doses; the other, little known, a slow, subtle, insidious saturation of the system by infinitesimal doses of lead extending over a long period of time, and producing a group of symptoms altogether different from the recognized forms of plumbism.

In the type of plumbism to which I refer there is rarely colic, seldom a blue line on the gums, and wrist-drop will occur only if the significance of the early symptoms is not recognized. There is rarely noticeable anaemia. I cannot say if an examination of the blood would reveal any approach to the blood destruction characteristic of the grosser forms of lead poisoning.

SIGNS AND SYMPTOMS

A strange lethargy creeps over the sufferer; he feels as if a cloud had settled over him; he loses interest in life; everything is a trouble—a weariness of flesh and brain. He prefers to sit over the fire to tackling his work, though when he forces himself through his tasks he finds no diminution of brain or bodily power. As the condition continues he becomes gloomy and taciturn. Instead of joining in conversation with relatives and friends he sits silent and apathetic, as if overcome by thoughts too melancholy to utter. All his faculties and bodily powers are sluggish. His bowels are constipated and stubborn, he derives no satisfaction from his food, and has perhaps abdominal discomfort, which he puts down to indigestion. The strange lethargy of body and mind increases. Sleep brings welcome respite, but he gets up tired and weary, as if he had not been to bed, though he has slept heavily all night; so tired, indeed, that to bathe, wash, and dress are ordeals he wishes he could shirk. Breakfast bucks him up, but during the day, oppressed with a weariness of body and misery of mind, and unaccountably tired, he succumbs to his desire to sleep. In neurotic females emotional outbursts, with flatulency and abdominal pain, may punctuate the melancholy.

Apparently lead puts a brake on metabolic processes. The listlessness may be due to deficient renal excretion or to a check to thyroid secretion. The hebetude is not unlike that of myxoedema, and I am sanguine enough to think that lead will lessen thyroid activity. The old doctors were not afraid to administer lead to their patients. The still officinal pil. plumbi cum opio was their favourite prescription. It has passed into the limbo of forgotten remedies, but it is possible that it might prove an efficient weapon in the hyperthyroidism of Graves's disease.

The patient gets no sympathy from those about him. If his expression is saturnine, his complexion is fresh and healthy, he sleeps well, forces himself to do justice to his meals, and his relatives set him down as a gloomy person who will not take the trouble to be chatty and lively. He is usually the only person in the house to behave so strangely, for lead has a selective action, and the freedom of others from symptoms increases contempt for the sufferer. Perhaps he sees a doctor, who suggests change of air. He goes away, and in a few weeks returns home a different man, full of life and energy, with all the

* Read before the North Wales Branch of the British Medical Association.

cobwebs cleared from his brain. But he soon loses the benefit of the change of air. The old lethargy and weariness overcome him again.

This is no fancy picture. I have myself twice suffered from this group of symptoms. Thinking that my bodily and mental hebetude were due to lack of it, I dosed myself with thyroid. That did not make me any brighter. Then, remembering my experiences in Huddersfield, where a soft moorland water caused lead poisoning, I had my urine and the domestic water supply tested for lead. The analyst reported that my urine contained 8/19 of a grain of lead per gallon, and the domestic water supply 1/14 of a grain. With the stoppage of the lead I soon regained my usual energy and good spirits. On going, however, to live elsewhere, the same bodily weariness and mental lethargy crept over me. I had the urine again examined, and it was found to contain 4/25 of a grain of lead per gallon.

Illustrative Cases

During my first attack I had under my care a young lady who, when well, was remarkable for her brightness and activity. A mysterious change had come over her. She was gloomy, taciturn, and miserable, and took no interest in the things which had formerly given her pleasure. She had attacks of a hysterical character, refused food from the discomfort it gave her, and suffered much from flatulence. After some ineffective treatment I had her urine examined. It contained 4/7 or about half a grain of lead in each gallon, and the domestic water supply 1/14 of a grain per gallon. She went away from home, returned her bright, active, healthy self, and with the stoppage of the lead has had no return of her symptoms.

Another case was that of a young doctor who went to live in the South-West of England. When he had been there some time he began to lose energy, and was always weary. He attributed the symptoms to the enervating climate of the South Country. When I heard that the water supply was a soft water I suggested that he should have his urine tested for lead. He scoffed at my suggestion. I have never seen granular kidney as a result of this type of plumbism, but in men who drank to excess I have twice seen lead encephalopathy with unconsciousness and convulsions, and when lead poisoning was prevalent in Huddersfield there was an unusual number of cases of puerperal albuminuria and convulsions. Lead, by slowing bodily processes and hindering metabolism, accentuates the liability of the pregnant woman, with her overcharged system, to develop albuminuria and convulsions. When I heard that this doctor's wife had been laid aside by puerperal albuminuria I told him my Huddersfield experiences, and urged him to have his urine tested for lead. This he did, and the analyst reported that it contained 1/10 of a grain of lead per gallon. Three weeks after the stoppage of the lead he wrote: "I am glad to say that since installing the filter I am much better, not so lazy, but there is still room for improvement." Six months later he reported himself as free from any symptom of plumbism.

After now to the possibility that lead might be the cause of his patients' symptoms, this young doctor had the urine of eighteen of his patients tested. In seven no lead was found, in one there was copper, and in the other ten quantities of lead varying from 1/125 to 1/5 of a grain of lead per gallon. Those in whom the larger quantities of lead were found improved after the installation of a filter.

Another case is that of an elderly maiden lady. Her chief complaint was that she was always tired. I begged her to have the urine tested. It was found to contain 8/9 of a grain of lead per gallon. This patient has high blood pressure, reaching at times to 252 mm. Hg systolic and 121 mm. Hg diastolic, a condition which I believe to be exceptional in this form of plumbism. Every year she has gone away, and has had treatment at Harrogate or Ruthin, always returning feeling better. Recently she went to Cheltenham for a month, and though she had no medical treatment, she returned from there feeling better than she had done for years. But with the return to the plumbo-solvent water, the old tired feelings set in again.

Diagnosis

This type of plumbism is so little known that it may be overlooked. One patient, whom I sent from home in order to get her away from the lead, was told by a doctor she consulted that she had never had lead poisoning, although lead in quantity was found in both her urine and the domestic water supply, and another doctor told a patient with wrist-drop that the cause could not be lead poisoning, as there was no lead poisoning in the place, although I myself had seen several cases of the type I have described. The symptoms are so different from the plumbism of textbooks that the cause may not be suspected.

The diagnosis of this insidious form of plumbism must never be made from symptoms. If the medical attendant suspects that lead is the cause of his patient's malaise he must not reveal his suspicions until he has verified them. He should ask for a specimen of the patient's urine, saying he wishes to see if the kidneys are sound. If on examination the urine is found free from lead and is otherwise healthy, the doctor has not compromised himself by a premature and mistaken opinion. Not until he has found lead in the urine should he question the purity of the water supply.

The problem is not easier because the symptoms can arise from other causes. When I lived at Criccieth I had an overpowering desire to sleep during the day, although I slept all night. An examination of my urine showed that it contained no lead, and the drinking water a fraction of lead too small to be harmful. My somnolence was due to septic teeth and tonsils. Suspicion should be aroused if a patient, whose water supply is soft, improves on being sent away, only to revert to his misery on returning home.

Nor must one forget that a patient who passes lead in the urine can be attacked by other disorders. A good many years ago I saw a man with symptoms pointing to overpowering of the nervous system, but not sufficiently distinctive to implicate brain or spinal cord. The late Sir Clifford Allbutt saw the patient with me, and, hearing that lead had been found in the man's urine and domestic water supply, agreed that lead was the probable cause of the man's condition. Signs of intracranial pressure came on later, with a slowly progressive right hemiplegia, and the man lapsed into the unconsciousness characteristic of cerebral tumour. I began intensive mercurial medication in the form of hypodermic injections of perchloride of mercury, and the man made a good recovery, with some loss of power in the arm and leg. It transpired that he had had syphilis.

It is impossible for one who is not a skilled analyst to test urine for lead. A few ounces should be sent to a competent analyst. Lead in the urine is a proof that it is in the patient's system. The quantity expelled by the kidneys is no indication of the amount of lead floating round the patient's system. It represents only the surplus percolating through the kidneys. It is the soft waters, especially those from peaty moorlands, which dissolve the lead of the service pipes, and so small is the quantity taken up that it may be years before symptoms arise. Before my attacks I had consumed the lead-laden water for at least six years. The young lady I mentioned had taken the same water for years. The young doctor did not complain for some years, and the elderly lady had been consuming lead-contaminated water for some years before her symptoms made me suspect the presence of the poison. Long-continued ingestion of the poison, in persons susceptible to its action, becomes in time the equivalent of a toxic dose. The presence of only one sufferer in a house is but an exemplification of lead's selective action, or of the inability of the sufferer's eliminatory organs to get rid of the poison.

MATERNAL MORTALITY AND LEAD

Important as are the effects of small doses of lead on health, they acquire added gravity as a possible factor in the causation of maternal mortality. The Registrar-General divides deaths in childbed into two groups: those from puerperal fever, and those due to "eclampsia and other accidents and diseases." Taking the country as a whole, puerperal fever is the most frequent cause of maternal deaths. In places supplied with soft moorland water the position is reversed. There, eclampsia and other accidents and diseases outnumber the deaths from puerperal fever, in some places by more than three times. In an appendix to her report on maternal mortality, Dame Janet Campbell gives the death rates of the Registrar-General's two groups for the four years 1919–22. During those four years the fewest maternal deaths from eclampsia and other accidents and diseases occurred in London, where they were 1.62 per 1,000 births. The London water, drawn largely from chalk-bearing strata, does not dissolve lead. In Dewsbury, Halifax, Huddersfield, Rochdale, and the county of Breconshire, supplied with plumbo-solvent water, the maternal mortality from the same causes was over 5 per 1,000 births, or more than three times that of London, while in Westmorland, Anglesey, Carmarthenshire, Caernarvonshire, Merionethshire, and Radnorshire, it was over 4 per 1,000 births, or about three times that of London. In the county of Westmorland, while there were three maternal deaths from puerperal fever, there were ten from eclampsia. The high maternal death rate from eclampsia and other accidents and diseases occurs where there is soft plumbo-solvent water. The main responsibility for this high death rate rests on eclampsia.

There must be some reason for the disparity between the figures for London and the places I have quoted. Other accidents and diseases of childbed cannot be more frequent in the places I have named than in London. The disparity is greater than the figures indicate, for the London figures are swelled by the cases of eclampsia which occur there. We know that lead is eliminated by the kidneys, and though I can produce no analyses of either blood or urinary urea, the sluggishness and somnolence I have described are not unlike the defective kidney action of Bright's disease. In its grosser forms of poisoning lead damages the kidneys, and more than one of my patients suffering from the subtle form of plumbism have had the nephralgia characteristic of the passage of gravel through the urinary organs.

Next to septicaemia eclampsia is the highest factor in maternal mortality. Knowing the symptoms which I have felt in my own person and observed in my patients, and remembering the frequency of eclampsia when subtle lead poisoning was prevalent in Huddersfield, the high mortality from eclampsia and other accidents and diseases of pregnancy in places supplied with plumbo-solvent water suggests that the continuous ingestion of minute quantities of lead may be the explanation of an otherwise unaccountable mortality. Though the quantity of lead imbibed may be small, it may be enough to turn the scale and precipitate the occurrence of eclampsia in a pregnant woman on the verge of toxaemia. If the conclusions I draw from the figures I have quoted are well founded—and they are confirmed by an examination of the death rates in other places too numerous for mention here—we have, ready to our hands, one means of reducing a great cause of the baffling problem of maternal mortality.

The remedy is simple—to stop the ingestion of lead. This can be done by sending the patient away from the lead, by substituting pipes lined with block tin for the lead pipes, or by passing every drop of water used in the preparation of food or for drinking purposes through a filter with a charcoal filtering bed. The so-called tin-washed pipes are not a protection, and only a filter with a charcoal filtering medium can be trusted to remove lead from a plumbo-solvent water.

Water supplies contain organic matter derived from the soil of the gathering ground, sometimes sufficient to discolour the water. In moorland waters there is an acid derived from the peat. The lead dissolved is not a simple inorganic salt, but a complex organic compound. It is by its affinity for organic substances that lead injures the body and destroys the embryo in utero. Charcoal, as we know from its effects in fermentative disorders of the digestive tract, attacks organic matter. In a carbon filter the fraction of organic lead in the water is acted upon by a mass of carbon compared with which a dose of charcoal by the mouth is insignificant. After from six to twelve months, according to the use it has had, the charcoal is not a reliable remover of the lead, and a fresh charge should be put into the filter.

No medicinal treatment is necessary to expel lead from the body. If the ingestion of lead is stopped and the eliminatory organs are active, the body will get rid of it. If iodides liberate lead from the tissues, the extra lead set free will aggravate the patient's symptoms.

SOME NEGLECTED SYMPTOMS IN ACUTE ABDOMINAL DISEASE*

BY

V. ZACHARY COPE, B.A., M.D., M.S., F.R.C.S.

SURGEON TO ST. MARY'S AND THE BOLINGBROKE HOSPITALS

Abdominal disease, whether acute or chronic, is diagnosed by considering three groups of observations. In the first place, local anatomical changes are detected by inspecting with the eyes or *x* rays, feeling with the fingers, or even by listening with the stethoscope; secondly, perversions of physiological function are deduced from certain symptoms indicative of visceral derangement or by carrying out certain tests which betray pathological changes in the abdominal organs; thirdly, when the disease is serious and is influencing the whole organism, note is taken of the great bodily systems, especially the circulatory, respiratory, metabolic, and excretory systems.

In chronic abdominal disease the slowness of the process allows time for compensation to occur; the slight physiological changes are masked or neglected until gross anatomical alterations may attract the attention of the observer, or the general bodily depreciation may be obvious to the patient and his friends. In acute abdominal disease physiological derangement plays a much greater part; rapid changes due to violent stimuli delivered without warning are the rule, and the need for immediate compensation of the vital systems is all too frequently unsatisfied; while gross anatomical changes either are absent or appear only at a comparatively late stage in the course of the illness. Unless these facts are appreciated diagnosis becomes haphazard and unscientific.

SIGNS AND SYMPTOMS OF SHOCK

It is well, therefore, to consider in the first place that symptom which is fairly common but still misinterpreted and ill-understood—that is, shock. When a sudden internal haemorrhage occurs, or when a very violent visceral stimulus is applied, the direct or reflex disturbance of the circulation leads to that clinical picture which is generally known as shock—cold extremities, subnormal temperature, pallor, sweating, a rapid and small pulse, and a lowered blood pressure. With a person who has been in

* An address to the Norwich Division of the British Medical Association.

good general health previously, however, compensation soon occurs, the circulation is soon re-established, and the observer finds it difficult to believe in the existence of any serious condition. Neglect to realize the wonderful compensatory mechanism of the circulation accounts for this misunderstanding.

Quite as serious is the failure to note minor degrees of shock. Shock is a clinical condition, and should not be defined too rigidly. When all the classical symptoms are present shock must be accounted extreme, but it may be present even when some of the symptoms are absent. Serious clinical shock may be present without pallor, without much increase in pulse rate, without much lowering of blood pressure; very seldom, however, does the temperature fail to be subnormal. Only when the diminution of blood volume becomes too great for the vasoconstriction to bring up the pressure to normal will the sphygmomanometer record a fall; but before that stage is reached the smaller blood volume may lead to diminished metabolism, lowered temperature, sweating, and other general symptoms. It is well in acute cases to take the blood pressure several times. It will then be seen that it may fluctuate rapidly, and that one record may give misleading information. Instability of blood pressure is characteristic of those degrees of shock which fall short of the full picture.

In the case of a perforated ulcer of the stomach or duodenum a greater or less initial degree of shock is generally present, but compensation occurs inversely as the violence of the injurious stimulus. With a small leak shock is almost absent; with a large one it may be extreme, and go on to a fatal result; with intermediate cases it is moderate and fairly soon recovered from. Its occurrence is even denied by some authorities in all cases; but a subnormal temperature, cold extremities, a sweating skin, and a pallid face are enough to diagnose clinical shock, and these are usually present for a time.

IMPORTANCE OF SPHYGMOMANOMETRY

The estimation of the blood pressure is too frequently neglected in other cases. Particularly is this the case in intestinal obstruction. The constant vomiting and direct effect of the toxins lead to a great fall in blood pressure. Unless this is carefully measured the capacity of the patient to undergo any operative procedure may be woefully miscalculated. With a blood pressure under 100 mm. Hg (systolic) it is seldom expedient to give a general anaesthetic. More important to recollect is the fact that the systolic pressure may be fairly high, but the difference between the systolic and diastolic small. This difference, representing the pulse-pressure which maintains the circulation, may be quite small, even though the systolic pressure may be approximately normal. I have recorded a case of intestinal obstruction in which the systolic pressure was 135 and the diastolic 110. This patient was in the last degree of collapse, and I gave it as my opinion that he would hardly stand enterostomy—an opinion which was unfortunately verified. You will note that the systolic pressure was maintained though the blood stream was dependent on a difference of pressure of 25 mm. of mercury for its propulsion.

PAIN

When we come to consider the symptoms due to physiological derangements pain is the most important. Indeed, it is often possible to diagnose a case merely by considering the type, intensity, and position of the pain. Too often, however, pain is inquired after in a very general sort of way, and important points are omitted. I will give some examples.

In the first place, help is gained by noting the shifting of the position of the pain. The best and most common example is that of appendicitis. The initial epigastric or umbilical pain is followed by the complaint of pain or tenderness in the right iliac fossa. This sequence is nearly always found in a first attack, but may be and generally is absent in later attacks. With a retrocaecal position of the appendix the initial epigastric pain is often absent. The epigastric-right-iliac sequence in a young adult or child nearly always signifies appendicitis, but in older persons greater circumspection is needed in diagnosis. A leaking duodenal ulcer or an attack of acute pancreatitis may give rise to similar, though usually more severe, pains. The shifting of the pain with a perforated ulcer is usually characteristic. At first severe and epigastric, it is followed by general hypogastric pain and tenderness.

In cases of peritonitis arising within the pelvis diagnosis may be difficult at first, but the pain gradually shifts upwards as the inflammation ascends, and the distension of the bowel is noticed at a higher and higher level.

Severe loin pain due to passage of small stone or gravel down the ureter is frequently accompanied by pain felt in the iliac fossa. If there is doubt as to the diagnosis (that is, whether appendicitis is the cause) help is gained by noting if the site of the pain tends to move downwards, as it often does with ureteric colic.

In cases of pancreatitis the initial devastating pain is followed by a more lasting pain and tenderness in both loins. If this pain were unilateral renal inflammation would naturally be suspected, but taken along with the character of the initial pain the bilateral loin pain is almost diagnostic of acute pancreatitis. It is merely a local pain due to the reaction round the swollen tissues of the gland, which, as we know, spreads its tail and head into the left and right loin just below the level of the last ribs.

Superficial Hyperaesthesia

Superficial hyperaesthesia is often present in acute abdominal disease and is occasionally of considerable value in diagnosis. It is folly to attach too much importance to it, however, for the same area of hyperaesthesia can be produced by various intra-abdominal lesions. Yet every symptom is to be investigated, and I am sure that this is sometimes neglected. In young people the right iliac triangle is confirmatory of appendicitis, while in older persons it is only found with that disease or salpingitis. The bilateral triangle may accompany hypogastric peritonitis, and occasionally is found before any obvious peritonitis has been set up by an appendicitis.

The narrow band of hyperaesthesia above and parallel to Poupart's ligament is commonly present in subacute and subsiding appendicitis, but may also accompany pyelitis, salpingitis, or even cholecystitis and perforated duodenal ulcer. It is due to irritation of the parietal peritoneum in the corresponding iliac region. In any case of doubt between a thoracic and an abdominal lesion the finding of iliac hyperaesthesia weighs down the scale on the side of an abdominal lesion. This alone would make it worth while to test for hyperaesthesia in every case.

Referred Pain

Of much greater value in diagnosis is pain that is felt outside the abdomen. Most of these pains are well known, so that everyone is aware of the site of pain due to colic of the small intestine, large intestine, uterus, or renal pelvis. But it is not generally known that disease of the appendix may cause pain in the testicle either of the same or the opposite side. This is an added difficulty in differential diagnosis, and one that may and has led to mistakes. The referred pain of biliary colic is usually

felt in the right subscapular region, but mistakes may result if one is ignorant of the fact that the pain may be felt anywhere in the zone of distribution of the eighth or ninth thoracic nerve. I have seen cases in which all the severe pain of biliary colic was felt in the left side of this zone.

Phrenic Shoulder Pain

That referred pain which I have found of most use in difficult abdominal cases is phrenic pain. Though I and a few others have been teaching the importance of this pain for several years the current textbooks make little or no mention of it, and certainly few make proper use of this symptom in their practice. I shall therefore dwell longer on this subject.

Phrenic referred pain is that pain which is felt on the top of the shoulder as the result of an irritative lesion in the region of the diaphragm. The phrenic nerve is made up of fibres from the third, fourth, and fifth cervical nerves, and the referred pain is felt in the region of distribution of the third and fourth, but chiefly the fourth, nerves. That area comprises the supraspinous fossa, the acromion and clavicular regions, and the subclavicular fossa. The loose way in which patients and doctors speak of the shoulder region when they actually mean the scapular or subscapular areas makes it necessary to specify top of the shoulder or tip of the shoulder pain.

The intensity and nature of the pain vary considerably. It may be so severe as to feel like a nail being driven in on top of the shoulder, or, on the other hand, may be so slight that the patient will not make any spontaneous complaint, and when asked about the pain will merely say that he had a pain in the shoulder which he put down to rheumatism. In a few cases the pain is felt in the deltoid region, and I have seen others where the patient stated that the muscles felt weak in that part.

Irritation of the right or left side of the diaphragm causes pain which is limited to the shoulder on the corresponding side; that is admitted by all. Inflammation in the middle part of the muscle may cause bilateral shoulder-top pain. In my experience there is also a further localizing value in this symptom, for I have found it a general rule, with few exceptions, that an affection of the anterior or posterior part of the diaphragm causes pain on the front or back part of the shoulder. For example, irritation of the anterior fibres of the muscle will cause pain in the clavicular region, while an affection of the crura will lead to local pain in the supraspinous fossa. There are few exceptions to this important rule.

Subdiaphragmatic Conditions

Phrenic shoulder pain is of the utmost value in fixing the site of many acute abdominal disorders. Scarcely a week passes that I do not find it of the greatest assistance. In the last fortnight it clinched the diagnosis in two cases—a ruptured spleen and an acute pancreatitis. I will indicate the class of case in which it is generally or occasionally present. There are two groups which we must distinguish. First, those diseases which originate in organs which are in relation with the diaphragm. Secondly, those conditions which arise in other parts of the abdomen but may affect the diaphragm secondarily.

The first group comprises diseases of the liver and gall-bladder, duodenum and stomach, spleen, pancreas, and, rarely, kidney. The most common disorder which gives rise to it is perforation of a gastric or duodenal ulcer. Phrenic pain occurs in about two out of every three such cases. In the case of duodenal ulcer the pain is most commonly felt in the right supraspinous fossa, as might be expected when we remember that the irritated part will be the right crus and contiguous part. Here I cannot help speculating on the reason for the origin of a curious error which has been and is being perpetuated from one textbook to another. It is stated with monotonous regularity that the pain of biliary colic is often felt on top of the right shoulder. Anyone who has observed his cases carefully over a number of years knows that, though such a reference of pain is possible, it is of the greatest rarity. Nearly every case of severe right hypochondriac pain associated with pain on top of the right shoulder is due to a leakage of a duodenal ulcer. Though I have known this for more than ten years yet on a few occasions I have discussed the diagnosis of a case with a practitioner and come to the conclusion that the rare exception of biliary colic with shoulder-top pain had at last turned up. In every case when I have operated later I have found a leaking ulcer. The writers who described shoulder-top pain in connexion with biliary colic put their views to paper before the surgery of acute abdominal disease had started, and I think that the error arose from mistaking the local leaking of an ulcer for gall-stone disease. If shoulder-top pain does occur with gall-stone disease it is almost always due to the onset of peritonitis which irritates the contiguous diaphragm.

With perforated gastric ulcer the pain is more often bilateral or felt on the left side. Occasionally it is limited to the clavicular region.

Tropical abscess of the liver is uncommon in this country, but phrenic shoulder pain is very common as an accompaniment of such an abscess. As a matter of interest it was through observing liver abscesses in Mesopotamia during the war that I was led to study the significance of pain referred from the diaphragm. When the symptom is present it signifies that the liver is adherent to the diaphragm and that the abscess is threatening to break through into the thorax. It is most often felt in the right supraspinous fossa, since abscesses usually affect the posterior part of the right lobe.

The occurrence of left shoulder-top pain in connexion with ruptured spleen is sometimes known as Kehr's sign. It is due to the irritation of the muscle caused by the effused blood.

Though it may not be accounted a surgical condition there is no harm in remembering that an infarct of the spleen may also be accompanied by phrenic shoulder pain.

Rarely acute pancreatitis may be accompanied by pain on top of the left shoulder localized to the supraspinous fossa. I have already mentioned a recent case that I have seen. I have seen one other similar case, and know of several more.

Very rarely perinephritis may irritate the diaphragm sufficiently to cause referred pain, but it is so rare and inconstant as to be of no practical value.

Pelvic Conditions

When we come to consider diseases originating away from the diaphragm the most important is ruptured ectopic pregnancy. The occurrence of shoulder-top pain in this condition has long been recognized, but its full significance is still far from being realized. The pain is due to the liquid blood flowing up to and irritating the diaphragm. It is a matter of chance whether the blood irritates the anterior or posterior part of the muscle, and so the position of the pain may be clavicular or supraspinous. There are few pathognomonic symptoms in surgery, but this can be regarded as a near approach—that is, severe collapse and hypogastric pain unattended by abdominal rigidity, but accompanied by pain on top of one or both shoulders, indicate a ruptured ectopic pregnancy or bleeding from a ruptured Graafian cyst. Even this well-established fact is not widely known. When peritonitis which has its origin in any part of the abdomen reaches up to the diaphragm it may irritate sufficiently to cause shoulder pain. As a rule, if such a case comes

on necropsy there will be found one or more plaques of plastic lymph between the liver and the diaphragm. This is more common on the anterior aspect, so the referred pain is more likely to be in the clavicular region.

I would not have anyone think that phrenic shoulder pain is ever to be relied upon to the exclusion of other symptoms, for the diaphragm has an upper as well as a lower surface, and thoracic disease may irritate this upper surface. That is only one more reason for making a thorough examination, so that no localizing sign may be omitted. It is worth mentioning that pain from diaphragmatic pleurisy is more commonly felt in the clavicular and subclavicular area.

Muscular Rigidity

I now come to the symptoms produced by the reflex rigidity of the muscles which bound the abdominal cavity. There should be little need to mention rigidity of the anterior and lateral abdominal muscles produced by peritonitis, since it is familiar to everyone who has seen half a dozen cases of acute abdominal disease. But it is not yet general knowledge—nay, it is often overlooked by the elect—that extensive peritonitis may exist without any rigidity at all.

At the risk of repeating what we all may know already I would point out that irritation of the internal lining of the abdominal cavity is responded to by a greater or lesser degree of rigidity of the muscles which wall in the cavity. There is a large area comprising the pelvic cavity and the median part of the posterior abdominal wall which is *relatively* insensitive or silent when stimulated, giving rise to no rigidity of the overlying or underlying muscles. It is very common to have early pelvic peritonitis without any muscular rigidity. Another fact which is overlooked is that old people with weak muscles and easily tired reflexes frequently show little or no rigidity with peritonitis.

Muscular rigidity of the deep-lying muscles is easily, and I think commonly, neglected. When the diaphragm is immobile on account of overlying inflammation we cannot always have an *x*-ray apparatus handy to show that it does not move on respiration, but we have an easy clinical test. If the abdomen is retracted with inspiration the midriff must be relatively immobile and is probably inflamed. This reversal of the abdominal wall movement is significant.

Psoas rigidity due to appendicitis or similar inflammatory condition in the vicinity is shown either by flexion of the corresponding thigh or by slight pain on moving the thigh. Slighter degrees may be detected by extending the thigh on the abdomen and noting if it causes pain.

It is seldom that the obturator muscle becomes rigid as the result of peritonitis, since the dense obturator fascia does not readily permit the inflammatory process to pass; but occasionally putting the obturator muscle on the stretch by inverting the flexed thigh will elicit pain and denote some overlying inflamed focus which is penetrating and affecting the muscle.

There is another little test which may be of some value in fat subjects with a suspected inflammatory mass in the region of the iliac fossa and vessels. If the fingers be pressed on to the femoral artery in Scarpa's triangle so as to stop the circulation in the limb, the extra pulsation in the iliac vessels as the result of the block may cause an increase of pain when the inflammatory focus is in contact with the vessels. This femoral test would only be of real use in very fat people, who are notoriously difficult to investigate.

Gross anatomical derangements, with the exception of torsion of viscera and strangled external hernia, are not often obvious in the early stage of acute abdominal disease. The presence of free fluid and free gas displaces and masks the parts, but usually at too late a stage to be of much practical value.

Conclusion

The diagnosis of acute abdominal disease is a fascinating art which may be almost made into a science by attending carefully to the manifold symptoms to which it gives rise. The problems greatly differ from those in chronic abdominal disease. The combat against disease is in the one case a siege and the other a battle, and different qualities are required for success. In the acute disease early appreciation of the menacing forces is essential, and success may sometimes be gained by paying attention to small points which would in a chronic disease be regarded as trivial. In no other class of case is time of such importance, laboratory assistance of so little use, and the opportunity for acute clinical observation so well provided. Though disappointment comes but too often, the reward of paying attention to some of the neglected points which I have mentioned is an increasing number of successful diagnoses, and, what is even more important, an inward sense of something logically attempted, something reasonably done.

ACUTE OSTEOMYELITIS OF THE ILIUM

BY

A. RENDLE SHORT, M.D., F.R.C.S.

SURGEON TO THE BRISTOL ROYAL INFIRMARY

Probably it falls to the lot of most general surgeons at some time in their work to meet with this disease, but it is certainly rather uncommon, it presents a very difficult problem with regard to treatment, and there is extraordinarily little to be found about it in surgical literature. A considerable search for what may have been published on the subject during the past thirty years has yielded very meagre results. A case was reported by Murphy in 1916, secondary to furunculosis. A case of osteomyelitis of the ilium, probably tuberculous, was described in 1930 by Ryan and Funston. At a Russian surgical congress at Leningrad in 1925 Krasnobajev reviewed 428 cases of osteomyelitis treated by him in twenty years, with a general mortality of 22.4 per cent. There were twenty patients with osteomyelitis of the ilium—that is, about 5 per cent. of the whole number—and of these eight died. It is therefore more dangerous than osteomyelitis of the long bones. Two patients suffering from this disease have lately come under my care.

Case I

Public school boy, aged 14. First seen July 19th, 1928, complaining of pain in right lumbar region attributed to a strain whilst diving two days before, when he "felt something go click." No physical signs, but limps a little.

July 20th.—Admitted to sanatorium. Has had no sleep on account of severe pain in buttock. Temperature 100°. Tender over right sacro-iliac joint. Temperature ran up to 102°, pulse 100; pain became very severe. Nepenthe gave no relief; no sleep.

July 21st.—Temperature 104.6°; very ill; pain and tenderness persist. Operation under novocain. Dorsum ilii exposed but not trephined; periosteum scraped through. One doubtful spot of pus seen.

July 24th.—Pain has been better, wound not suppurating. Temperature 103°-104°. Leucocytes 11,000; 89 per cent. polymorphonuclears. Mercurochrome given intravenously.

July 27th.—Abscess of right buttock opened. Culture: pure *Staphylococcus aureus*

July 30th.—Temperature 102°. Pain in chest; rub. Diagnosed by Dr. Carey Coombs as pericarditis. Abscess of left buttock opened under novocain.

August 11th.—Swinging temperature has continued. Pleuritis and pericarditis stationary. Abscess in front of right iliac bone opened; small crumbling patch of bare bone found.

September 15th.—Pus in left hip-joint, with pathological dislocation. Opened by Mr. C. F. Walters in my absence.

October 15th.—Head of femur excised; through-and-through drainage of hip-joint. Did well for a time, and temperature became normal.

November 10th.—Fever again. Tube put through hip-joint.

January 1st, 1929.—Temperature has remained up. Abscess under left iliacus muscle opened. Better for a week, then temperature 102°.

January 12th.—Pus in left knee-joint evacuated.

March 21st.—Went home, improving, temperature normal.

For a long time there was a persistent sinus over the hip-joint, but eventually this healed, and the patient is now very well.

Summary.—Boy, aged 14. Acute osteomyelitis of ilium, followed by pericarditis, pleurisy, abscess under each iliacus muscle; pus in hip-joint necessitating removal of head of femur; pus in knee-joint. Very ill six months; nine operations. Recovery.

CASE II

Hospital nurse, aged 23. Seen October 2nd, 1930. History of pain in left buttock for a week, really bad for twenty-four hours, and extending down sciatic nerve. No sleep on previous night on account of pain. Temperature 100°–101°. Vomited once. Pain now severe. On examination tenderness over the left sacro-iliac joint. No pain on "crowding" iliac crests; hip-joint moved normally. Per rectum, *nil*.

Operation, incision down to iliac bone in tender area. Outer plate of bone removed over an area one and a half inches across. Marrow looked normal, but culture showed Gram-positive staphylococci, and pus cells present in smear.

October 5th.—Pain much better. Temperature 104°–105°. Delirious at times.

October 6th.—Very ill; delirious. Pleuritic rub.

October 10th.—Purpura. Pleuritis and pneumonia in both lungs.

October 12th.—Died. No necropsy.

Summary.—Nurse, aged 23. Acute osteomyelitis of ilium; bone opened by operation. Pain relieved, but died of pyaemia and septicaemia.

DISCUSSION

In both cases there was a period of several days, three in the one and seven in the other, during which the patient had pain in the buttock, gradually getting worse. There was no known septic focus. The boy thought he had strained the back. Next came violent and persistent pain, unrelieved by opiates, with a rise of temperature, and marked deep tenderness of the dorsum ilii. If the surgeon recollects that there is such a disease as acute osteomyelitis of the ilium the diagnosis is not difficult.

The disease is apt to be severe, running a prolonged course, with numerous complications, both early and late, and considerable danger to life. Both my patients became exceedingly ill with pleuritis; one had pericarditis. The patient that recovered had abscesses in front and behind both iliac bones, and in the hip- and knee-joints. A case is, however, known to me in which a quiet abscess formed in the ilium, necessitating operation, but going on to recovery. This may correspond to the condition known as Brodie's abscess in the long bones.

TREATMENT

This presents a very difficult problem, especially on the day that the diagnosis is first made. The pain is so severe that opiates give no relief, and everybody is very anxious that something should be done to relieve tension. Operation does certainly make the pain better, but during the next few days the patient is likely to be very ill. In my opinion the opening up of cancellous tissue by removing the outer layer of the iliac bone did indeed reduce tension and allay pain, but precipitated pyaemic symptoms by opening up the veins in the cancellous spaces to infection. There is nothing abnormal to see, so one does not know how much cortex to remove. It seems better, therefore, in an acute case, to treat it as the schoolboy was treated, by draining down to, but not into, the bone, under a local anaesthetic, in the hope (probably vain) that pus will be found under the periosteum. Mercurochrome may be given intravenously to combat septicaemia. Abscesses about the os innominatum must be expected, constantly watched for, and opened when they are found.

SUMMARY

In one published series of cases of acute osteomyelitis of various bones the ilium was involved in 5 per cent., with a mortality of 40 per cent.

Two cases are described, one fatal, one recovering after a long illness and many operations.

The diagnosis is not difficult; several days' pain in the sacro-iliac region; then violent pain, raised temperature, and deep tenderness.

The best treatment is probably to incise down to, but not into, the bone.

THE PROPHYLAXIS OF TUBERCULOSIS OF THE LARYNX

BY

H. MORTIMER WHARRY, F.R.C.S.,

SURGEON, DISEASES OF THROAT AND EAR, BOLINGBROKE HOSPITAL

Tuberculosis of the larynx is so frequent and so fatal a complication of phthisis that any suggestions for preventing its occurrence, or for securing treatment in its early stages, should be given consideration even if there is no proof that they will necessarily prove effective in all cases. There is abundant proof that in its early stages this complication can be arrested, and in many cases cured, by certain definite measures. These are:

Rest in a sanatorium.

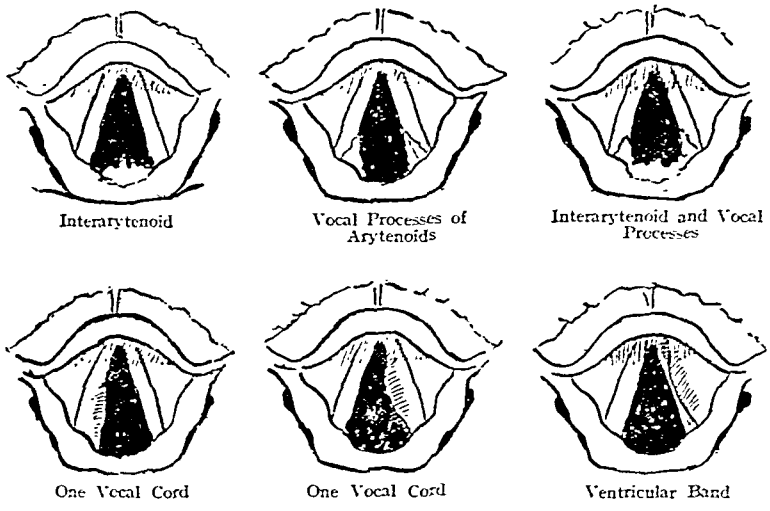
The restriction of the voice to a whisper over a period of some months.

Complete silence for a similar period.

The elimination of sepsis in the upper air passages, because it is well known that any septic process tending to produce laryngitis, whether acute or chronic, affects adversely the progress of laryngeal tuberculosis.

The prevention of cough. By this I mean unnecessary, harsh, and irritable cough producing an unnecessary strain upon the vocal cords.

As long as the pulmonary lesion is chronic it has generally been found that these measures are effective in arresting, and finally curing, a majority of cases of early chronic laryngeal tubercle. It may be necessary to supplement these conservative measures by more active treatment such as cauterization under local anaesthesia, but, generally speaking, the larynx will respond to such treatment if the condition of the lungs is not progressive or fatal. This being so it seems justifiable to draw certain conclusions which may give some indication of how to



prevent the incidence of this complication. Measures which will bring about a cure in early cases may be relied upon to prevent occurrence when applied to any patient with certain reasonable modifications according to the practical possibilities in each individual.

REST IN A SANATORIUM

Where this is indicated, on account of the condition of the lungs, there is no need to stress the point on account of the larynx, but where there are any indications that a phthisical patient has a larynx which is not quite normal he or she should go to a sanatorium if possible, even if the condition of the larynx is not definitely diagnosed as being tuberculous.

RESTRICTION OF THE VOICE

This is a matter of considerable difficulty in patients who are endeavouring to lead a normal life; nevertheless it is important that patients with pulmonary tuberculosis should restrict the use of their vocal chords. Tuberculosis of the larynx is of somewhat frequent occurrence among clergy, street criers, and those whose occupation necessitates continual loud speech, and the occurrence of pulmonary tuberculosis among these is often first indicated by an early laryngeal lesion. Patients should be warned that excessive use of the voice is accompanied by a definite danger to themselves, and the doctor in charge of every case of pulmonary tuberculosis should satisfy himself that no undue strain is being put upon the larynx. This may be a difficult matter where a patient is obliged to use the voice continuously in his daily occupation, but even in such cases some modifications are often possible.

EARLY TUBERCULOSIS OF THE LARYNX

ELIMINATION OF SEPSIS

I have always attributed the greatest importance to this form of treatment because I have found gross sepsis of the teeth and tonsils in a large percentage of patients. At the Mount Vernon Chest Hospital, before its conversion to a hospital for cancer, it was a matter of common experience to examine twenty new cases of tuberculous laryngitis and find that fifteen of them were affected in this way. I have seen cases where the pulmonary lesion was rapidly healing, but where the larynx, under the influence of gross dental sepsis, had become affected by a combination of tuberculous and pyogenic infection, which finally caused a fatal termination to an otherwise favourable condition. To my mind, sepsis of the upper air passages is often a deciding factor in the progress of a case, but I have heard that some observers look upon it lightly.

THE PREVENTION OF COUGH

In all cases cough is necessary for the expectoration of sputum from the lungs. But in many instances an irritable condition of the fauces, pharynx, and larynx leads to the development of a cough which has no practical usefulness, but merely damages the larynx and permits of its invasion by tubercle bacilli in the sputum. This type of cough can readily be restrained by suitable palliative measures, which are too well known to enumerate. It seems reasonable to suppose that attention to detail under the above headings may, in many cases, prevent the occurrence of this very serious and justly dreaded complication.

In addition to these measures it appears to be important that every patient with pulmonary tuberculosis should be subjected to examination of the larynx at regular intervals, which may be decided upon for each individual. Diagnosis in such cases cannot be made too early nor can treatment be applied too soon. Immediate admission to a sanatorium is indicated as soon as a diagnosis is made, because it is quite as necessary for laryngeal tuberculosis to be treated in a sanatorium as for any other kind. If possible, the urgency in the case of the larynx is greater. It is almost impossible to persuade anyone to undergo a long period of silence which is necessary to produce a cure without the supervision, discipline, and restraint which can only be applied effectively in a properly organized institution.

The illustrations show some of the most common forms of early chronic tuberculosis of the larynx. The treatment of this condition has already been outlined in general, but special methods may justifiably be used in special circumstances; these are as follows:

1. The galvano-cautery. The application of the galvano-cautery to a laryngeal lesion is made under deep cocaine anaesthesia. It should not be made until the lesion has been quiescent for some months. It has the effect of replacing tuberculous granulations by scar tissue. It has certain disadvantages, because tuberculous patients do not always tolerate the application of strong solutions of cocaine, nor are they always unaffected by the slight shock and mental strain in which submission to a rather difficult manipulation involves them.

2. Radium. The success which has attended the radium treatment of lupus of the upper air passages encouraged me to use it in quiescent cases of laryngeal tuberculosis. Its action is similar to that of the galvano-cautery because it stimulates the granulation tissue to form scar tissue. It is more thorough than the galvano-cautery because it is applied from the outside and leaves no part unstimulated. It is less drastic than the galvano-cautery because it produces no fierce local lesion and needs no local anaesthesia. But, like the galvano-cautery, it is a weapon which should be used only by a specialist who has watched the progress of the case and feels certain in his own mind that the condition is quiescent and that the time has come to take an active step in treatment.

A NEW METHOD OF TREATMENT OF THE FRACTURED CLAVICLE

BY

JAMES KEMBLE, CH.M., F.R.C.S.

CHIEF CLINICAL ASSISTANT, WEST LONDON HOSPITAL

The multiplicity of the methods employed for the treatment of the fractured clavicle bears witness to the want of satisfaction which is so often felt in dealing with this common lesion. Owing to its peculiar location and to the unique mechanical purpose which it serves, a clavicle which shows any residual shortening after fracture occasions a very appreciable impairment of the strength and functional utility of the upper limb for a considerable time after the accident. Moreover, since in women décolletage is an established fashion, any mal-alignment will jeopardize the prospects of cosmetic perfection. In introducing this new mode of treatment I am convinced, after reviewing my series of cases, of the simplicity of its application, of the comfort afforded the patient, of the more perfect alignment obtainable, and of the definite curtailment of the period of incapacity occasioned by the injury.

CLINICAL FEATURES

The cause of these fractures is almost invariably indirect violence due to falls on the hand, the elbow, or the point of the shoulder. It is applied, as a rule, to the under surface of the outer end of the clavicle in an upward and inward direction, the relative magnitude of the upward and inward components varying in different cases.

The actual fracture occurs most frequently at or near the junction of the inner two-thirds and the outer third. This is the point of meeting of the two curvatures of the bone. Moreover, the inner two-thirds of the bone, constituted by the anterior convex curve, is cylindrical in form, and consists of a compact layer of considerable thickness. It therefore resists a fracturing force more effectually. The fracture may be of the "greenstick" type, this being common in young children. The angulation is directed upwards and forwards. Of the complete varieties the line of fracture may be transverse or oblique, the latter being the commoner. In the majority of cases, the obliquity takes a direction from above downwards, inwards, and backwards. The position taken up by the bone ends relative to one another is due partly to the direction of the violence and partly to the weight of the limb. The inner end of the outer fragment comes to lie below and in front of the outer end of the inner fragment. The whole outer fragment also moves inwards, so that the bone ends overlap. Other deformities occur, but are less common. In the most common type of lesion—the oblique fracture with the deformity described above—the part played by the violence in determining the direction of the fracture and the displacement of the ends is probably the same as in the case of the abduction-eversion fractures at the ankle. In the case of the clavicle, the coraco-clavicular ligaments act as a fulcrum, and the force applied to the under surface of the outer end of the bone produces an oblique fracture to the inner side of the ligaments, with the characteristic displacement. In the case of the ankle the abduction-eversion force driving the astragalus outwards against the external malleolus causes an oblique fracture of the fibula some two inches above the inferior tibio-fibular ligaments, which act as the fulcrum. The other factor producing and maintaining this position of the bone ends is the weight of the limb. The whole outer fragment drops. Moreover, as the main function of the clavicle is to buttress the shoulder outwards and backwards, when a fracture occurs, the outer fragment of necessity moves inwards and forwards.

TREATMENT

A satisfactory method of treatment must take cognizance of every one of these facts regarding the fracture. In dealing with all fractures the three principles of treatment are: first, the reduction; secondly, the retention of the corrected position; and thirdly, the maintenance of nutrition and early restoration of functional utility.

In the case of the clavicle, reduction is always easily accomplished. It is the retention which has always presented the difficulty.

To retain the position after reduction, some means must be utilized which will prevent the outer fragment from moving inwards, forwards, and downwards, and will at the same time act as a splint between the two portions of the divided bone. Moreover, the upper limb must be left free. In many of the methods which have been used, especially that known as Sayre's, the whole upper limb, including the hand, was fixed against the side and front of the chest by firm strapping or bandage. The patients always complained of great discomfort, the skin became sodden from perspiration, or blistered from strapping, while the greatest objection of all was the stiffness of the whole arm and hand, which was the outcome of the immobilization and disuse. This prolonged the period of incapacity very appreciably. Other methods, such as those depending merely on loops passed round the shoulders and tied across the back, were ineffectual. A secure and effectual retention of the reduced fracture must be ensured, not only on account of the great likelihood of recurrence of the deformity in this situation owing to the mechanics of the part, but also owing to the saltatory and restless disposition of the young patients in whom fractured clavicles are most common. The method must be essentially simple in application, owing to the ubiquitous incidence of this type of fracture and the everyday circumstances under which it occurs. It must be available to the general practitioner as well as to the surgeon. For this reason any elaborate appliance which involves the use of steel frames, fitted splints, or extensive plaster jackets is impracticable. Recumbency is undesirable. Open reduction with the introduction of a plate or intramedullary peg, though it may give ideal alignment, is as unnecessarily drastic as it is wantonly disfiguring.

I have therefore attempted to meet these exigencies by the utilization of a moulded plaster-of-Paris slab. The technique is as follows:

Make a fairly thick elongated slab by sandwiching several layers of plaster-of-Paris bandage between two layers of lint. This slab is roughly rectangular in shape,

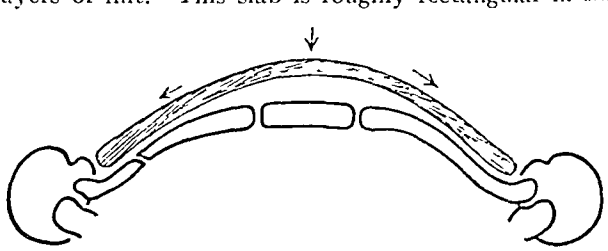


FIG. 1.—Diagram demonstrating the moulded plaster slab in position

but is somewhat wider at the ends than at the centre. It is made to an exact size for each case. Its length is one inch greater than the distance between the delto-pectoral folds in front of each shoulder. It is 4 inches wide in an adult and proportionately narrower in infants. When the precise position of the fractured ends in the radiogram have been recognized the patient is seated on a backless chair. An assistant stands behind the patient, puts his left knee between the shoulder-blades, and with the fingers of either hand in front of the shoulders, draws them firmly backwards, outwards, and upwards. The

surgeon stands in front and manipulates the fragments till reduction is perfect. The assistant retains this by maintaining the traction.

The plaster slab is then applied by the surgeon in front. Each extremity is moulded so as to be crutch-ended and to fit into the delto-pectoral hollow in front of each shoulder. It is made to come well down into the axilla beneath the shoulder so as to obtain sufficient upward lift. Owing to the prearranged length of the slab, the central part, which is in front of the sternum and inner portions of the clavicles, is bowed out from the skin surface slightly. Over the outer half to two-thirds of the clavicle the slab is moulded exactly to the contour of the bone in its corrected alignment. It thus embraces the fragments on both sides of the fracture. The plaster is held till set. A nurse then applies bandages in the following fashion. First, a double "figure of eight" is applied round both shoulders, with the intersection in front over the centre of the slab. The assistant then relinquishes his hold. The effect of this bandage, very firmly applied, is to exert a force backwards, outwards, and upwards on the centre of the bow-shaped slab. The plaster here stands off a short distance from the sternum, so that this pressure is transmitted through the crutch-ends of the slab and *pushes* the shoulders and outer ends

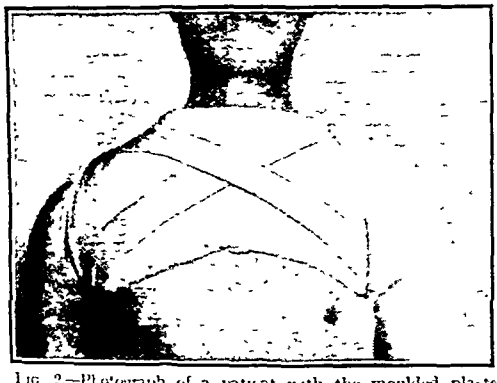

FIG. 2.—Photograph of a patient with the moulded plaster slab in position.

of the clavicles backwards, outwards, and upwards. The slab acts, indeed, exactly as an adventitious clavicle, replacing the bone both in position and function as closely as is possible. It constitutes an efficient substitute till the continuity of the prototype is restored. Properly applied, this bandage is sufficient, for the slab maintains the shoulders in the braced back and supported position, when the assistant relaxes his hold. It is best, however, in order to ensure immobility of the plaster, to apply another "figure of eight" bandage round the shoulders, with the intersection behind. The portion of the slab which has been moulded so as to lie in intimate coaptation with the clavicle over the site of fracture acts as a perfect splint, preventing any possible movement at this point. The arm is supported in a sling at first, though this is not always necessary, and the patient goes home. The movements of the shoulder are partly restricted, but the rest of the arm and hand are perfectly free for use. The plaster is retained for from ten to fourteen days. Throughout, the patient is perfectly comfortable, and on removal of the slab finds he has full movements of the whole limb.

In the series of cases treated by this method a radiogram has been taken in every patient after reduction and application of the plaster. This has confirmed a satisfactory reduction.

SUMMARY

The advantages and results can therefore be summarized thus:

The method is simple.

It is effective in securely retaining perfect alignment after reduction, so that a gratifying cosmetic result is assured, and there is no risk of disability due to residual shortening of the bone.

The patient is completely comfortable throughout the treatment, and has free use of his hand and arm.

As a result of this last circumstance the period of incapacity due to the accident is considerably curtailed by the employment of this technique.

For the opportunity of carrying out this investigation I wish to express my gratitude to Mr. Sangster Simmonds, whose clinic at the West London Hospital these patients have attended.

RENAL COLIC AND HAEMATURIA FOLLOWING RECUMBENCY

BY

W. ETHERINGTON WILSON, F.R.C.S.

TORQUAY

During the latter period of the great war many of the hospitals were made into centres where certain types of gunshot wounds were concentrated for reasons of efficiency and team work. The 1st London General at Camberwell became one of the centres for fractured femurs, and it was among these cases that I came across a remarkable series of cases of renal colic and haematuria. Of some hundred and fifty men who passed through the special femur wards I have notes of twenty-three who exhibited this renal complication. I publish them now because I have often been asked about them, and hope that they may be of some assistance to research workers on kidney disease and function.

I have to admit from the outset that many investigations were incomplete and left undone at that time in trying to find a cause for the colic and bleeding, but I am convinced that, had *x* rays been used, a larger number of urines examined carefully, or cystoscopies undertaken, no assistance would have been forthcoming in elucidating these phenomena.

It is necessary to draw attention to the following facts. (1) These were all femur cases, and were treated by the Sinclair method. (2) All the patients remained recumbent on their backs for periods varying from three to twelve months or more. (3) The foot of the bed was raised at least nine inches during the earlier weeks of their period of treatment—that is, the stage of extension. (4) Most of the patients concerned were kept recumbent for a long time on account of severe wounds, prolonged sepsis, delayed or non-union, or other wounds. Only one had a simple fracture with delayed union, and he was treated on a net bed, with the usual sloping feet-upward position. (5) When union was considered firm (normally two and a half to three and a half months) a walking calliper was fitted, and the men allowed up on crutches fifteen minutes or so on the first day. On the second day they were allowed to be up longer, and it was remarkable how much they did get about on their feet. I have known one of them to be seen walking in the corridor as if he had been up for a fortnight. Eagerness, competition, and the cheers and envy of the less lucky ones in the ward were, of course, responsible for these feats. It was on this day that several cases of renal colic with haematuria occurred. (6) With regard to the amount of sepsis present, small sinuses in the thigh, sequestra, and flaring-up of healed wounds were common occurrences. The more serious acute septic conditions—that is, secondary haemorrhages, blood infections, joint infections, etc.—did not occur in any of the present twenty-three cases under consideration. (7) Concerning diet, there was an abundance of greenstuffs eaten by the men at dinner, and it is perhaps wise to remember that during the period 1918-19 our vitamin stocks were probably somewhat lacking. (8) The total number of cases of renal colic and haematuria of which I have some record and

were seen by me number twenty-three. Actually there were probably three or four more, one or two occurring in the wards of other members of the staff and others in my own; but of these I have no record, and they will not be included.

RENAL COLIC

This symptom was present in all the twenty-three cases, and represents 15 per cent. of the total number of fractured femurs treated during a period of nearly two years. The attack was similar in most of the cases, the differences being only one of degree. The pain was usually intense and sudden in onset, beginning as an anterior or posterior renal pain and radiating down to the groin; some had pain referred to the penis tip, and a temporary frequency was manifest. The sisters of the ward got used to seeing them, and often reported that So-and-so was having an attack of renal colic. Haematuria followed nearly all these cases. One dose of morphine, and bed eased the pain, and the attack was never repeated immediately. The next day the right abdomen and renal region were tender, the kidney was felt to be enlarged in a few of the cases, and the patient still felt uncomfortable. By the third day the tenderness had nearly all gone, and no complaints were forthcoming. The renal colic always occurred on one side only at the time. Ten cases are recorded of the attack being right-sided and six left; the others are not noted. In two cases the attack was bilateral, but with an interval of three months in one case and several days in the other between the two sides.

The exact period in the treatment when the first attack of renal colic occurred is interesting. In sixteen cases the pain came on after being out of bed and assuming the upright position. Of these, two occurred on the first day up, nine on the second day (when a good deal of walking was invariably done), and five are noted as being later still—for example, many days up to three weeks. One of these latter patients got a violent attack of renal colic with profuse haematuria while out on pass away from the hospital.

Six men got renal colic while still in bed, but they were all able to sit up and move about, the foot of the bed had been lowered, and the main extension and fixation of the splint removed. The period of recumbency varied very much—the shortest case, and one only, was three months. Another case occurred after four months. In eighteen cases the average period in bed was nine months, the shortest of these being six and the longest about fifteen months. In three cases I have no note of the period, but none was less than three months. In three cases the appendix was removed—in all, I believe, in error—in cases of right-sided renal colic; in two of these I saw neither the attack nor the operation, but ascertained that the appendix did not account for the pain, and the men developed haematuria. The third patient was operated on one evening when I was absent for the day; the appendix was normal, the kidney was discovered to be much enlarged, and blood was found in the urine in large quantities; this man developed renal colic three weeks after being up, the attack occurring outside the hospital whilst he was on pass.

HAEMATURIA

In sixteen cases out of the twenty-three there was an obvious haematuria visible to the naked eye, one-quarter to one-half of the urine glass on standing containing red corpuscles. In six of these cases I note that the bleeding was profuse and alarming for the time being. The passage of blood clearly accounts for the renal colic in these cases. Within forty-eight hours the urine was very much clearer, and by the third day there appeared to be little or no blood in a fresh specimen, but the microscope showed the presence of a few red cells. The attack of haematuria usually passed off in almost as dramatic a way as it first began. In one case there was some bleeding which continued for a week, though lessening in amount daily. In four further cases there was microscopic blood, but this was not obvious macroscopically, making a total of twenty cases of haematuria. In three patients I have no note of the condition of the urine.

The Question of Calculi.—One patient with a profuse haematuria passed three or four small friable calculi. He got a recurrence of renal colic later, and passed some gravel. He was the only one of the series where lithiasis comes into the question. He was a badly wounded man, with an additional gunshot wound of the hip-joint, and had a very long period on his back in bed, with persisting local chronic sepsis.

Urine.—I only have the record of ten urines examined, and they do not help very much; in all but two the cultures were sterile; one, probably a contamination, grew staphylococci, the other staphylococci, *B. coli*, and diphtheroids. Oxalate crystals (a few) were reported in two cases. The usual report was: red cells +++, white cells one or two, albumin +, cultures sterile, no casts or crystals seen. In two cases it was shown that by the fourth day after the attack all the red cells had disappeared.

X Rays.—A very small proportion of these cases were *x*-rayed, with negative results.

Recurrence of Attacks.—Two and a half years later I sent a questionary to most of these men, and got seven replies. They had all remained quite free from urinary symptoms except one man, who recorded five attacks of colic—two in 1919 while in our hospital (one when he was up, the other in bed), and attacks in 1920, 1921, and 1922. *X*-ray examination at Bristol revealed nothing. This was one of the cases where organisms were grown from the urine, and there is no report of haematuria. I think it probable that he was not of the same type of case as the others. Four other patients got one recurrence of renal colic with bleeding.

DISCUSSION AND SUMMARY

During 1918 and 1919 15 per cent. of the patients in the femur wards developed renal colic, the actual pain being probably due in the majority of these cases to the passage down the ureter of large quantities of blood. It was manifest that this occurred, in most of the men, on assuming the upright position after prolonged decubitus. What was the explanation of these frequent incidents? Infection must, I think, be ruled out: first, because of the frequency with which sterile urines were reported; secondly, one case was a simple fracture, the result of an aeroplane accident, with no wound or sepsis at all; thirdly, it was very noticeable that nearly all the cases of renal colic occurred suddenly on getting up on the first or second day, and just as quickly got well again, without running temperatures or having rigors, or, indeed, having any further trouble up to two and a half years afterwards.

There was no evidence in any of the cases, except one, of calculus formation. This patient did pass calculi, and in a later recurrence passed gravel. It is not surprising that at least one patient should develop calculi; for does it not seem that the conditions were ideal for stagnation in the renal pelvis—for example, the prolonged dorsal position in bed with foot of bed raised, and in most of the cases chronic septic wounds continuing over a greater part or all of this period? Indeed, at one period the idea of calculus formation was uppermost in my mind. There was no evidence that such stagnation occurred, or that the possible products of such a condition—organisms, debris, crystals, etc.—passed down the ureter

and gave rise to pain and bleeding. There was no evidence at all to suggest that these were cases of oxaluria, only "a few crystals" being reported in two specimens. I eventually came to the conclusion in 1919, and still think, that the great majority of these cases, at any rate, developed painful haematuria because of postural conditions, the sudden assumption of the upright position in too great a hurry being the deciding factor. Few of the other members of the staff had the same experiences, probably because the fractured femora were mostly concentrated in special wards; these men had to lie on their backs for long periods, and, further, the colic cases occurred among the chronics of these wards. Mr. Harold Wilson, who was responsible for the beginning of the femur work, will remember the first few cases of renal colic, and our apprehension after a time as to whether So-and-so would get an attack on his second day up. It is apparent that the kidneys became engorged with blood, for there was evidence of enlargement of the organ, by palpation from without, and in one case from within, the abdomen. It is probable that this renal congestion was allowed by the temporary loss of vasomotor control and dilatation of the renal vessels and the other great vessels of the splanchnic area on assuming the erect position. The same explanation holds good in the patient who feels faint on getting out of bed after an illness, a temporary anaemia of the brain being produced.

At first it would appear that such an explanation is adequate, but does it completely clear the ground so easily? Why did no patient develop a bilateral renal epistaxis at the same time? It is not likely, however, that this would occur, for if both kidneys became congested at the same time, and the right began to bleed first and cause pain, would it not act as a safety valve? Moreover, the patient would have been put to bed, the engorgement pressure being further relieved, and the left kidney saved from any degree of haemorrhage. Some five attacks of colic occurred in bed, either as a first attack or a recurrence. The explanation here is not easy, but only in one of these cases was the patient necessarily on his back; the remainder had reached an active stage of moving about and sitting up in bed. One man developed renal colic three weeks after getting up, as mentioned already, for which his appendix was removed and a large right kidney palpated at operation, haematuria being noticed after operation. This is another type of case difficult of explanation. May it not be that there were two types of renal congestion, acute and chronic—the patients who were up on their feet too suddenly, and bled as the result, being included in the acute variety, those who remained free of actual visible haemorrhage for a few days, in the chronic? Is it possible that the devitaminized cells of the renal tubules or capillaries allowed more easily the burst of blood through into the kidney pelvis?

I am firmly of the opinion that had we got these men up more gradually, and had they not been so enthusiastic in showing what they could do on their feet at such an early stage, fewer cases would have been recorded. Painful renal haematuria occurring after a recumbency, as far as I know, is not a common disorder. Did other medical officers have any such similar experiences during those years, or have any cases been seen and recorded in civil practice?

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

AN UNUSUAL CASE OF AMNESIA

Loss of memory after head injuries is by no means rare; amnesia, of greater or less extent, being an essential feature of concussion. Yet the following case merits attention by reason of three unusual points—namely, the latent period between the original injury and the commencement of the amnesia, the duration of the condition, and the dramatic results following surgical intervention.

On August 8th, 1930, a man was found wandering the roads in an exhausted condition, and brought to the hospital. He was very collapsed from exposure and malnutrition, and was treated for shock. He could give no account of himself, and there were no marks of identification on his person. Careful nursing and prolonged convalescence restored his physical condition. He was a well-set-up man in the prime of life. On examination an old depressed fracture, about the size of a half-crown, was found in the right parietal bone, situated midway between the fontanelles and about two inches to the right of the mid-line. There was a faint crescentic scar in the skin over this region. The patient was unable to remember anything whatever of his life previous to his admission, nor could he remember his name, age, or profession. It was thought that he might have been a sailor, owing to his being able to "box the compass"—that is, recite the points of the compass in their order round the dial of the instrument. He took a great interest in his condition, and was desperately anxious to discover his identity and recover his memory.

The skull was examined by x rays, and a large depression of the inner table was found, with a layer of new bone formation beneath, extending into the extradural space and for some distance round the site of fracture. It was decided to operate. On November 28th, a large whole-scalp flap was turned back, exposing the entire depressed area and a wide margin of healthy bone. Four trephine holes were made and connected up by Gigli saw-cuts on three sides, forming a square flap. The bone flap was thus raised and removed. The subjacent dura mater was at first immobile, but in a few moments commenced to pulsate. The wound was cleaned up with saline, and the scalp flap closed, a small rubber drain being left at one side. The patient's condition remained good throughout the procedure.

On recovering consciousness he thought that he was in hospital in Shanghai, and was rather restless and worried because "his ship was due to sail in the morning." By next morning his condition was excellent, and he was able to give the following account of himself. He was in truth a seaman in the Navy, and had been in a ship on the China Station in 1920. While ashore one night he became involved in a brawl, in which he (so he was afterwards told) received a blow on the head, and was taken to hospital at Shanghai. He was treated for four to six weeks, and then sent back to his ship. No operation was performed. He continued to serve on the station till 1926, in which year his term of service was up, and he was sent home to be paid off. His last recollection was leaving Port Said, and he remembers being on duty in the morning watch when the ship sailed. His next—waking up in hospital here after his operation. He has no remembrance of the intervening period.

The patient's progress has been steady, apart from occasional headaches. He is now beginning to get up, and says he feels very well. We have had many interesting talks upon Navy subjects, and it is evident that he is perfectly familiar with the routine, and all that pertains to it, of life as a bluejacket. One may also add that the relatives have been to see him and have identified him, and that their story of his absence coincides in every way with his own account.

Commentary

1. Have we operated upon a case of hysteria? The answer to this, I think, is to be found in the character of the patient, which is the very reverse of anything approaching that of a neurotic. Also, though closely observed and questioned both before and since his operation, he has remained entirely consistent in his behaviour and statements.

2. This case would seem to emphasize the importance of operating on all depressed fractures in adults as the patient's condition permits.

F. B. MALLINSON, M.R.C.S., L.R.C.P.
Pembury Infirmary, Kent.

EXTRACTION OF BROKEN CATHETER FROM URETHRA AND BLADDER

A man, aged 64, called me at midnight as he had broken his catheter while attempting to withdraw it after use. The catheter was an ordinary rubber one, size 10, and the patient had been in the habit of using one for some years.

On examination the broken end of the catheter could be felt about 2½ inches from the meatus, and manipulation was tried to work it to the exit. The patient informed me that he himself had tried for half an hour to work it out. While this was being attempted by me he told me that six years previously, while in the United States of America, a similar thing had happened, about 2½ inches having broken off and being left in the bladder. For ten months a "doctor tried to dissolve it with medicine." Subsequently he returned to Swansea, where a suprapubic cystotomy was performed, and the missing portion of catheter, now somewhat encrusted, was removed. After a long convalescence he recovered, but continued to lead a catheter life, without any other symptoms until the present catastrophe.

Half an hour's manipulation having failed, I applied an ordinary pair of sinus forceps, one blade being introduced into the lumen of the catheter and the other between the catheter and the mucous membrane. After a long and careful pull the missing portion was recovered in its entirety. A very strong "grip" was noticed in the region of the stricture. The piece extracted was 9¾ inches long, the external portion being 9¼ inches.

Swansea. L. W. HEFFERMAN, M.R.C.S.

PROLONGED ANURIA WITH RECOVERY

The following case appears worth recording on account of its rarity.

Mrs. A. Q., aged 53, was admitted to hospital on September 1st, 1930, complaining that she had passed no urine for two days. Three years previously she had had a panhysterectomy and bilateral salpingo-oophorectomy for uterine fibroids. In 1929 she had suffered from a slight "stroke," but had completely recovered. A few weeks prior to admission she had noticed haematuria on two occasions. For two days before admission, in addition to anuria, she had had no bowel action, and vomiting was occurring frequently, the vomit being green and offensive. During the previous day she had been strange in manner, had complained of headache, and had been muttering in an incoherent fashion.

On examination the temperature was 99°, pulse 80, and respirations 24. The general condition was very poor, the colour greyish, the skin dry and hot, and the tongue thickly coated. The abdomen was moderately distended, with tenderness and rigidity in the left loin, but the bladder was not palpable. A catheter was passed, but the bladder was quite empty. The blood pressure was 185/105. The patient was treated with an alkaline diuretic and diaphoretic mixture, hot packs, pilocarpine, and drastic purgatives, but no urine was passed, and the general condition became much worse. Thirty-six hours after admission, despite the high blood pressure, a pint of intravenous saline was given, but this did not stimulate the kidneys to secrete. In order to eliminate calculus anuria an *x*-ray of the urinary tract was made, but this was negative.

By September 4th the condition had become critical, the patient vomiting repeatedly and being semi-comatose. The blood urea was 282 mg. per 100 c.cm., and the systolic blood pressure had risen to 195 mm. On this day 14 ounces of urine were passed, and the amount varied during the following days, until an average of 30 ounces per day passed. Examination of the first specimen of urine showed: cloud of albumin, urea 2.3 per cent., chlorides 0.29 per cent., and a deposit of red blood corpuscles, granular casts, and epithelial cells.

By September 11th the blood urea had fallen to 169 mg., by September 18th to 82 mg., and by October 16th to 46 mg. The blood pressure fell to 135 mm. on September 11th, and then gradually became stabilized at the level of 150 mm. The patient was discharged in very good health seven weeks after admission.

This case is, in my opinion, one of anuria occurring in chronic interstitial nephritis, and it is worthy of note because it is rare for a patient to suffer from complete suppression for five days, culminating in a blood urea of 282 mg. per 100 c.cm. and then to recover.

I have to thank Dr. W. G. Bendle for permission to publish this case.

Paddington Hospital, London, W.2.

Reports of Societies

OXFORD OPHTHALMOLOGICAL CONGRESS

The twenty-first annual meeting of the Oxford Ophthalmological Congress was held on July 9th, 10th, and 11th. Members met informally at dinner on July 8th in the Hall of Keble College, which again offered its hospitality. The advantage which is gained by the all too short stay in the college, where each member is assigned rooms, and becomes for the time being a student again, is one of the features of this successful gathering, which was instituted by the late Robert Doyne in 1910.

The congress was held in the department of human anatomy of the University, kindly lent for the purpose by Professor Arthur Thomson. In addition, there was a commercial exhibition in the scientific museum, where numerous well-known firms of ophthalmic instrument makers displayed the latest forms of apparatus and instruments. As usual, a large number of foreign and overseas members attended, which emphasized once more its international character. The proceedings began on July 9th with a short address of welcome from the deputy master, Mr. PHILIP ADAMS, who announced, much to the regret of all present, that, owing to indisposition, the master, Mr. Bernard Cridland, was unable to preside.

Mr. LESLIE PATON opened a symposium on the diagnosis of intracranial new growths, dealing especially with the ophthalmological aspect. He said that ocular signs were among the most important in the diagnosis of cerebral tumours. He considered changes in the nerve head of primary importance, next alterations in vision and the visual fields, ocular palsies and nystagmus, and changes in the pupil reactions. He considered papilloedema the most important sign of the presence of increased intracranial pressure. Of less significance were the symptoms of headache and sickness. Increased retinal arterial pressure, as first pointed out by Dr. Bailliart, preceded papilloedema. Unequal papilloedema was rare, and might be due, as suggested by Dr. Walter Parker, to unequal intraocular pressure. Mr. Paton said that optic atrophy might result from pressure consequent on papilloedema.

Inequality of the pupils was not of great diagnostic value, but might indicate the site of the lesion. Ocular palsies were important for localizing purposes. He commented upon the complexity of the tracts and centres involved in nystagmus, and on the numerous sites of the lesion.

Sir PERCY SARGENT said that the aim of diagnosis should be, not merely to localize, but to ascertain the type of tumour. Some general sort of classification was necessary, the best one being a combination of the topographical and the historical. Pituitary hyperplasias, suprapituitary tumours, and cerebello-pontine tumours constituted three readily recognized groups. The speaker discussed the endotheliomata and gliomata, emphasizing the point that the former were encapsuled and always outside the brain, whereas the latter were always in the substance of the brain. He described the diagnostic points of the rarer forms of intracranial tumours, such as parasitic cysts, cholesteatomata, haemangiomata, etc. Finally, he said that chronic abscesses, tuberculomata, and gummata should be included under tumours, seeing that their symptomatology might be indistinguishable from that of true neoplasms. Dealing with the diagnosis of the tumour, the speaker said that mechanical and other adventitious aids to diagnosis should be adjuvant, and not alternative.

Dr. H. M. TRAQUAIR stressed the value of perimetry, and discussed the positive information which is obtained when the visual pathway is affected. He emphasized the importance of thorough testing of both fields by the quantitative method, and the necessity for careful study of all the characters of a field defect.

Mr. NORMAN DOTT estimated highly the value of perimetry to the neurological surgeon, saying that it might constitute the main or only evidence of the lesion. He stressed the importance of a correct knowledge of the interpretation of the perimetric findings, which, he said, should be correlated with the other factors in the case.

The discussion was continued by Professor Dr. ARTUR SCHÜLLER of Vienna, who gave a most instructive address on the radiological findings in cerebral tumours, and showed how the many pitfalls could be avoided in these cases. Professor EMIL DE GROSZ (Budapest), Mr. HARRISON BUTLER, Dr. GIRI, Dr. TYSON (New York), Dr. WALTER PARKER (Detroit), and Mr. STAMMERS also joined in the discussion.

In the afternoon Professor G. ELLIOT SMITH, F.R.S., gave a very interesting address on the evolution of the instruments of vision, tracing the developments of the eye from its earliest forms.

Demonstrations in the scientific museum were given by Mr. BURDON-COOPER on irradiation of cataractous and other lenses; Mr. GEORGE YOUNG showed a specimen of bilateral haemorrhages into Cloquet's canal; Miss MARGARET DOBSON demonstrated her binocullariscope; Mr. WHITTINGTON a new device for the training of squinting children; Mr. ARTHUR GREENE a specimen showing idiopathic panophthalmitis with unusual features; and Mr. C. G. RUSS WOOD specimens of epithelioma of the corneal limbus and papilloma of the caruncle.

The annual dinner of the congress was held in Keble College in the evening, and was attended by a large number of members and their guests. Mr. PHILIP ADAMS proposed the toast of "The Oxford Ophthalmological Congress." He stated that the membership was now over 150, and that twenty new members had joined since last year. The toast of "The Guests" was proposed by Mr. ARTHUR GREENE, and responded to by Sir FARQUHAR BUZZARD.

On the second day Dr. BAILLIART of Paris gave a very interesting and exhaustive address on tonometry. He described the various methods of ascertaining the intraocular pressure, and dwelt on the important points of tonometers. He considered that an international standardization of tonometers was desirable. The relation between the blood pressure and the ocular pressure was considered of great importance; the two should always be compared. Dr. Bailliart pointed out that the intraocular pressure was modified by the application of the tonometer. He considered that tonometric variations in pressure were extremely important, as they gave valuable indications of the intraocular circulation, and that in the case of glaucoma they were of prognostic value.

The Doyne Memorial Lecture was given by Mr. PHILIP ADAMS, and was entitled "An ophthalmological melange." This consisted of a most interesting series of experiences of common and rare cases seen over a space of many years. At its conclusion Mr. CYRIL WALKER, the master-elect, who presided at the lecture, expressed his warm appreciation when presenting the lecturer with the Doyne Memorial Medal.

Dr. HARALD GJESSING of Drammen, Norway, gave the result of the after-examination of 122 eyes which had been operated upon by Holth's iridencleisis.

Mr. JAMES CRAIG introduced a discussion on penetrating wounds of the eye. He dealt with the various ways in which a penetrating wound might injure the eye, and the evil effects of prolapsed iris. He mentioned the wounds of the ciliary region and of the sclera. He stressed the danger of retained foreign bodies, and discussed their varying effects, mentioning the methods of removal. Mr. Craig discussed the question of foreign bodies in the vitreous, and the symptoms of intolerance of the eye for them. He described the methods of removal with the magnet, also the extraction of non-magnetizable foreign bodies, and the special therapeutic measures for treating the wounded eye. Professor SCHÜLLER followed with an illuminating description of the various methods of localizing foreign bodies in the globe, and pointed out that the expensive forms of apparatus for doing so were unnecessary, equally good results being obtained by simple methods.

Mr. RUGG-GUNN read a very interesting and practical paper on contact glasses. He discussed the theory of their action, and mentioned many practical points with regard to their application.

Mr. BERNARD CRIDLAND presided at the meeting on July 11th. On rising to open the session he received a very warm welcome.

Dr. BERNARD SAMUELS of New York read a paper on the methods of formation of the posterior abscess in ulcus serpens. This was fully illustrated by many excellent slides. Dr. CRISP of Denver read an interesting and practical paper on the use of cross cylinders in refraction work. He pointed out that not only were they very useful as regards the estimation of the strength of the cylinder, but also that the position of the axis could be determined more accurately by their use. Mr. GEORGE YOUNG made a communication on recession of the internal rectus muscle, describing both the theoretical and practical aspects of the operation. Mr. NICHOLAS HUGHES read a very interesting paper on thirty-seven cases of macular disease in children. In the large majority of these, defective vision had come on after an attack of measles. Professor CURRAN of Kansas City read a paper on 400 operations of peripheral iridotomy in acute and chronic glaucoma. His special method of doing the operation was fully described, and the results were detailed.

The congress, which was attended by over 120 members, was generally considered to have been the most successful of the series, both in the high scientific value of the papers read and in the large attendance.

Reviews

ANATOMY IN THE LIVING MODEL

Anatomy in the Living Model,[1] by Professor DAVID WATERSTON, is the outcome of a desire to link together the facts of anatomy as displayed in the dissecting room with the facts to be observed in a living model, both at rest and in action. It is, however, something more. It is the outcome also of a desire to explain various phenomena—as, for instance, the restriction in certain movements of the fingers, the cutaneous lines of cleavage to which Langer has drawn attention, the mottling frequently noticed of the skin—by references to macroscopical or microscopical anatomy. Such features, but particularly the attention paid to the change which takes place in surface form in passing from rest to action, serve to differentiate it somewhat sharply from most if not all of the publications with which we are acquainted on the subject of surface anatomy.

The volume is divided into three parts: a relatively short but interesting chapter on the skin, in which such matters as the intimate structure of this covering, the question of nerve and arterial areas, and the localization of touch, pain, and warm and cold spots are discussed; a final short appendix of practical exercises on subjects like the taking of finger-prints and the electrical stimulation of nerves; and an intermediate section, forming by far the major portion of the work, subdivided into four sections dealing respectively with the topographical anatomy of the arm, the leg, the head and neck, and the thorax and abdomen. It is this last section which conforms most closely to what we regard as orthodox anatomy. It will be noted that the author has carefully refrained from describing his work as an "applied anatomy," and throughout has approached his subject from the standpoints of the anatomist and physiologist rather than from those of the surgeon and physician. The two latter, particularly the orthopaedist and neurologist, will, however, find in the book information of value and importance. For a first edition the work is singularly accurate: it is also relatively exhaustive, but we have noted a few omissions. For instance, in the account of the carrying angle at the elbow no reference is made to the part played by the anconeus in its production. The outward curvature of the radius for the better mechanical advantage of the pronator teres is remarked, but the corresponding inward curvature for the similar advantage of the antagonizing supinating muscle, the biceps, is ignored. Again, while the sharp setting back of the base of the second metatarsal is mentioned, the almost equally sharp setting back of the bases of the fourth and fifth metatarsals is not.

The illustrations, many of which are coloured, are both numerous and excellent, the wash-drawings of the modelling of the limbs and the figures of certain sections of the head and neck being, in our opinion, particularly meritorious. We think everyone will be grateful, too, for the figure of the facial musculature of a European male drawn from a specimen in the anatomy department of the University of St. Andrews. A few of the smaller and simpler figures are, however, not above criticism. For instance, the insertion of the tendon of the tibialis posticus muscle in one of the figures is incompletely shown, and that of the tendon of the peroneus tertius inaccurately. In Figure 1 the position of the sebaceous gland in relation to the arrector pili muscle, though corrected in the legend, is liable to convey a wrong impression.

Such criticisms as we offer here are obviously concerned with matters of minor importance, and in no way materially detract from the value of the work. The author has brought to his task the fruits of a wide and long experience as well as of careful and considered thought, and has succeeded in producing a volume of much originality and suggestiveness.

FIRST LINES IN ANAESTHESIA

Dr. W. S. SYKES has written a somewhat unconventional short textbook in his *Anaesthesia*,[2] which is the latest addition to Dr. Crookshank's Modern Treatment Series; but there is no doubt that his method will impress first principles very clearly upon the minds of his readers. He begins with a chapter called "The Foundation Stones of Safety," which (like the Lamps of Architecture) are seven in number. All seven are certainly fundamentals, but we should have liked to see a keystone added, impressing the young anaesthetist with the importance of choosing the safest method which will afford the surgeon proper facilities for the procedure he is about to employ. Elsewhere the author is properly emphatic on this very important principle; but he omits it in this chapter, where, above all, it should be made prominent.

The instruction offered to the student and the very junior practitioner, for whom the book has been designed, is clear and practical, as well as thoroughly up to date. It is a pity, however, that a piece of lint, or a doubled-up corner of towel, should be put forward as adequate vehicles for the administration of chloroform; they may be traditional makeshift substitutes for a proper mask, but surely should not be held out as anything more than rather risky improvisations which are occasionally useful in emergencies. How many face burns, or even corneal ulcers, to say nothing of still more serious anaesthetic catastrophes, these Victorian contrivances have caused one shudders to think of; but they still seem to have adherents, judging by some recent textbooks.

Dr. Sykes is rather sceptical about one or two fashionable developments of technique; he doubts the advantages of making the patient recovering from anaesthesia inhale carbon dioxide gas, and he is also not impressed by the virtues claimed for warmed ether vapour. It is refreshing to find an author bold enough to tilt at what he regards as passing fads; and it is conceivable that in a few years the favour with which some anaesthetists regard these procedures will have given place to indifference or even opposition. Within the severe limitations of space imposed upon him, Dr. Sykes has produced a really useful workaday outline of his subject.

PSYCHIATRY

The tenth volume of the *Archives of Neurology and Psychiatry*,[3] which is issued from the Central Pathological Laboratory of the London County Mental Hospitals at the Maudsley Hospital, includes a number of important and interesting pathological, psychological, and clinical studies, some of which may be said definitely to illuminate the obscure problems of mental disease. The first contribution is a concise summary of the conclusions arrived at as the result of a series of researches carried out under the direction of Dr. F. L. GOLLA on the pathology of schizophrenia. The details of this work are given in the seven papers which follow the summary. Since these

[1] *Anatomy in the Living Model*. By David Waterston, M.D., F.R.C.S.E., F.R.S.E. London: Hodder and Stoughton, Ltd. 1931. (Pp. xvii + 255; 74 figures, 16 plates. 25s. net.)

[2] *Modern Treatment: Anaesthesia*. By W. Stanley Sykes, M.B., D.P.H., M.R.C.S. With a Section on Local Anaesthesia by P. J. Moir, M.C., M.B., F.R.C.S. The Modern Treatment Series. London: J. Cape. 1931. (Pp. 128; illustrated. 5s. net.)

[3] *Archives of Neurology and Psychiatry*. Edited by Frederick L. Golla, M.B., F.R.C.P. Vol. x. London: P. S. King and Son, Ltd. 1931. (Illustrated. 15s.)

pathological studies have been published from time to time in various medical journals, it will be found very helpful to those who are interested in the problem with which they are concerned to find them collected in one volume. Briefly, these researches lead to the view that in the schizophrenic a failure of acid-base equilibrium exists, the determining factor of this condition being a lowered excitability of the respiratory centre to the stimulus of carbon dioxide. Dr. Golla states that the waking condition of such patients appears to resemble closely that of the normal person during sleep—an interesting generalization since, on the psychological side, it has often been noted that the psychic productions of the schizophrenic are analogous to those of the dreamer. It is to be hoped that further studies of this kind may be undertaken, since they not only throw some light on the pathology of schizophrenia, but also make it permissible to nourish the hope that treatment along biochemical lines might some day be applied with success.

In the sphere of normal psychology Drs. Golla and S. Antonovitch give an account of a particularly ingenious and interesting experimental study on the respiratory rhythm in its relation to the mechanism of thought. Studies were made on the respiratory volume and rhythm by means of a plethysmograph enclosing the whole body. Two types of habitual respiration emerged: an irregular respiratory type in subjects with predominantly auditory imagery; a regular type in subjects with predominantly visual imagery. It is interesting to note that the two types are approximately equally distributed among normal subjects of both sexes. On the clinical side we have an important article by Dr. E. Mapother emphasizing the need for accuracy in the assessment of alcoholic morbidity. Mr. C. Geary records observations upon the histopathology of general paralysis treated with malaria and relapsing fever; Dr. W. A. Caldwell reports on 579 cases of general paralysis treated by malaria in the London County Mental Hospitals; Dr. T. Tennent gives an account of investigation into the prolonged treatment of general paralysis with tryparsamide; and Dr. S. A. Mann and Mr. F. Partner deal with the question of the Wassermann reaction in mental hospital practice.

Altogether the volume contains twenty-six papers. It is evident that much active and fruitful investigation is being carried out in the laboratory, and that the high standard of the work is still being maintained.

INTERNATIONAL TRADE IN DRUGS OF ADDICTION

The League of Nations has issued for the use of the Conference on Limitation of the Manufacture of Narcotic Drugs an analysis of the international trade in morphine, heroin, and cocaine for the years 1925–29.[1] The ultimate object of the analysis was to arrive at the quotas of the world's legitimate requirements to be assigned to each manufacturing country. That objective appears, for the present, to have been set aside by the Conference, inasmuch as the quota scheme has been rejected. A not less important, and indeed a more immediate, aim of the analysis was to elucidate the extent and source of the illicit traffic in the drugs in question.

The task assigned to the "Opium Traffic and Social Questions Section" of the secretariat of the League in preparing this volume of 215 pages and five statistical tables with explanatory notes was a formidable and laborious one. While in some cases returns have not been forthcoming, and in others their accuracy is not beyond doubt, the analysis furnishes abundant material on which to base more effective endeavour to limit the production of narcotic drugs to the amounts required for medical and legitimate purposes. As regards exports, it appears that Germany was responsible in the years 1925–29 for 41.5 per cent. of the 40,783 kilograms of morphine exported from the eight manufacturing countries, and for 62.3 per cent. of the 16,642 kilograms of cocaine so exported in those years; while Switzerland supplied 41.7 per cent. of the 22,545 kilograms of heroin exported in the same years from the eight manufacturing countries. The heroin exported from Switzerland was consigned chiefly to France and the Netherlands. Since 1926 no heroin is reported to have been exported from the United States, where its manufacture is forbidden. The cocaine exports from Germany went to almost all the non-manufacturing countries, and in large amounts to Switzerland. When comparison is made between the returns of imports into certain countries with those of the exports thereto grave discrepancies are revealed, due, it is suggested, either to illicit traffic or to incorrect returns. During 1930 these discrepancies are stated to have been fewer and less in amount than in previous years. Uncertainty as to what is done with illicit drugs which have been confiscated is another possible source of the discrepancies disclosed in the stocks as accounted for. The explanations vouchsafed by various countries of the discrepancies in statistics revealed by the investigations of the secretariat of the League leave a good deal to be desired.

The last table (Table V) gives the conclusions of the whole study, and was intended, not only to serve as a basis of the present legitimate trade, but also to facilitate the allocation of quotas of production among the eight manufacturing countries. It accordingly indicates "how large a proportion of the exports of each manufacturing country should be lopped off as having been feeding the illicit traffic." From this table it appears that as regards morphine, while none remained unaccounted for at the end of the five-year period (1925–29) in the case of Great Britain, 36.33 per cent. was unaccounted for in the case of France. As regards heroin, the figures are 13 per cent. for Great Britain, 53 per cent. for France, 23 per cent. for Italy, and 74 per cent. for Austria. With regard to cocaine, while for Great Britain 2 per cent. remained unaccounted for, for France 24 per cent., for Japan 23 per cent., and for Austria 28 per cent. were the corresponding figures. The argument for some approximation to the action taken by Great Britain under the Dangerous Drugs Acts, 1920–25, in fulfilment of treaty engagements by several of the other signatory Powers, could hardly be made more complete than it is as set out in this comprehensive analysis.

PROSTHETIC DENTISTRY

In conjunction with forty-five collaborators, Lieutenant Commander NICHOLS of the Dental Department of the United States Naval Medical School has compiled a volume, entitled *Prosthetic Dentistry: An Encyclopedia of Full and Partial Denture Prosthesis.*[2] The major part of the book, dealing as it does with "mechanical dentistry," will necessarily be of greater interest to the dentist than to the medical practitioner. The medical reader, however, cannot fail to be impressed by the fact that the dentist needs an intimate knowledge of the anatomical and physiological details of the parts he is dealing with before he can hope to construct an efficient replacement apparatus, as well as an expert knowledge of the materials he is using in the workshop. In

[2] *Prosthetic Dentistry: An Encyclopedia of Full and Partial Denture Prosthesis.* By Ira Goodell Nichols, D.D.S. With collaboration of forty-five authorities. London: H. Kimpton. 1930. (Pp. 687; 839 figures, 3 plates. 50s. net.)

addition to normal prosthesis there is a valuable section devoted to showing what useful work can be done in facial restoration by a combination of the surgeon's skill in plastic operations on the soft parts and the dentist's ability to supply an apparatus replacing the lost hard tissues. Indeed, we think many patients might prefer this combination as a shorter cut to health and work than is provided by bone grafting.

There is an interesting note on the torus palatinus by George M. Dorrance, who discovered references to it as far back as 1814, and mentions that it sometimes has to be removed to ease the patient's fear of cancer, but he finds that it carries with it no trace of a "stigma of degeneration." The book is well and profusely illustrated, and should appeal to all interested in mechanical dentistry, and, we may add, to all engaged in "Service" dental work.

NOTES ON BOOKS

The National Association for the Prevention of Tuberculosis has published a new edition of its *Handbook of Tuberculosis Schemes*.[6] This very useful book forms a complete directory of tuberculosis work throughout the country. Each administrative area in England, Wales, Scotland, Channel Islands, Northern Ireland, and the Irish Free State is dealt with separately; such details as general and tuberculosis death rates, provision for treatment under the tuberculosis schemes, and the administrative staff, are included. The *Handbook* forms the only published list of tuberculosis officers, and the only complete list of residential institutions for tuberculosis. It includes also charts showing the comparative rates for respective counties and county boroughs, the fall in the tuberculosis death rate, etc. Orders should be sent to the secretary, N.A.P.T., Tavistock House North, W.C.1, with remittance for 5s.

In a monograph, entitled Women and the Progress of Medical Science,[7] Dr. MELINA LIPINSKA shows the part played by eminent women in various countries in the advancement of medicine from the earliest times until the present day. The work is divided into five parts, devoted respectively to primitive medicine, antiquity, the Middle Ages, modern times up to the nineteenth century, and the nineteenth and twentieth centuries. The last part will naturally attract most readers, as it deals with the successful struggles made by women in various countries to obtain admission to medical faculties and the part played by women in the great war. The work is illustrated by numerous portraits, including those of Lady Mary Wortley Montagu, who introduced inoculation into Western Europe, Madame Necker, who did much to reform French hospitals, Miss Nightingale, Madame Dejerine, the neurologist, and Dr. Josephine Ioteyko, the Polish psychologist and patriot.

Dr. AIGLRNON WEAR, in the *ABC of Child Health*,[8] has set out for the use of the intelligent mother some elementary facts about the common diseases of childhood, as well as much straightforward advice on hygiene and first aid. The aim, as Dr. Wear says in his preface, has not been to turn the mother into a doctor, but to set out in simple language the facts about the health and well-being of children which should be the common knowledge of every mother. For this reason he makes little or no reference to treatment, except in cases calling for emergency remedies until the arrival of the doctor, such as burns and scalds. The book should be useful for reference among mothers who wish to know something of the causes underlying childish ailments.

[8] *ABC of Child Health*. By Algernon Wear, C.M.G., M.D., B.S., D.P.H. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (Pp. 81. 1s. net.)

The tenth edition of *A Simple Method of Water Analysis*,[9] by Drs. J. C. THRESH and J. F. BEALE, has now appeared. Medical officers of health will find in it some definite improvements on previous editions, though little change has been necessary in the description of the chemical methods of water analysis, apart from certain practical suggestions for simplifying the procedures. All the helpful features of previous editions have been retained, but condensation has obviated any increase in the size of this popular handbook.

The Animal Year-Book[10] is the annual review of the University of London Animal Welfare Society. This body has been formed to enlist educated opinion in the cause of humane treatment of animals. It is important to note that it is not an antivivisection society; it is working on broad common-sense lines for such objects as humane slaughter, improvements in methods of trapping, proper disposal of oil-waste from ships, and so on, with a remarkable freedom from the overstatements which in the past have characterized such societies. The *Year-Book* reviews the work being done, the problems requiring immediate attention, and the more important publications on the subject which have appeared within the last decade or so. There is also an interesting article on the clinical work of the veterinary colleges, and on anaesthetics and narcotics in animal medicine and surgery.

PREPARATIONS AND APPLIANCES

TRAY FOR RADIUM NEEDLES

Mr. EDGAR FRESHMAN, F.R.C.S. (London Hospital), writes:

The following tray, which has been made to my specification, has proved useful for carrying radium needles that are threaded prior to sterilization. It is of metal, 15 inches long and (including the side handles) 12 inches broad; the angle at which the handles are placed enables it to be completely immersed in one inch of fluid. Each needle with its thread is held by a peg and a spring clip, of which there is a row of twenty-four near each end of the tray. The needles, after being threaded, are placed so that one of the double threads issuing from the eyes passes over each side of a peg; the threads are then pulled taut and fixed in the corresponding clips at the other end of the tray. The pegs and

clips are placed so as to take threads of not less than 10 inches in length, but the tray can be made to accommodate needles with shorter threads. If the threads are knotted a little distance from the needles it is simpler to draw the knots, rather than the eye ends of the needles, up against the pegs. The advantages of this tray are that on each one twenty-four needles can be carried, sterilized, and counted with ease and convenience, and with the minimum amount of handling. All annoyance due to entangling of the threads is avoided, and only a very small depth of fluid is required for sterilization—an important point if this is effected by immersion in spirit. The tray has been made for me by Messrs. Allen and Hanburys Ltd., Wigmore Street, W.1.

THE FACTOR OF INFECTION IN THE RHEUMATIC STATE

In his new monograph[1] Dr. Alvin F. Coburn, resident physician of the Presbyterian Hospital in the City of New York, defines what he means by the "rheumatic state." It is clear that he includes within this term the same group of phenomena that is in this country sometimes labelled "acute rheumatism," but better described as juvenile rheumatism or the rheumatic infection. This picture, as Dr. Coburn sees it in New York, is a little less precise than that which is apparent to clinical observers in the British Isles, and the colours are rather more vivid. These differences are probably real. The infection as it is seen in New England is more florid than in this country, and therefore produces phenomena over a wider range of organs, and of an intenser degree in the same organs. The New York lesions, however, conform in their anatomical and histological patterns to the criteria for which we are chiefly indebted to the British observers—a debt which Dr. Coburn acknowledges in generous terms. Our understanding of this "rheumatic state" has within recent years entered on a new phase. The end of the nineteenth century, with all its new bacteriological knowledge, brought a conviction of the infective nature of acute rheumatism. Since the twentieth century opened there has been a slow but steady set of opinion towards support of the view, first enunciated by Poynton and Paine, that the infection is streptococcal. The present times are witnessing attempts to solve two further questions: What kind of streptococcus is responsible, and by what means does it make its attack?

Dr. Coburn has addressed himself to the solution of these problems by means of researches as ingenious as they are thorough. The conclusion to which he comes is that "the rheumatic process is a human reaction, which appears in susceptible individuals, and which represents a special type of tissue response to chemical substances arising from disease of the upper respiratory tract. That unrecognized infective agents may be associated with these upper respiratory diseases is possible; nevertheless, the findings in this study justify the conception that *Streptococcus haemolyticus* is an important factor of infection in the rheumatic state." He does not find that this organism can be recovered from the circulatory blood in acute rheumatism. His claim to its recognition rests on the results of his laborious researches into the flora of the upper respiratory tract, especially of the pharynx, and into the reaction of the skin to inoculation with nucleoproteins of bacterial origin. The cultures made from throats both of rheumatic and of other patients in New York display a seasonal rise in the prevalence of *Streptococcus haemolyticus*, but no such rise occurred in Porto Rico, where this organism is seldom encountered in the upper air passages. Rheumatic patients taken from New York to Porto Rico soon lost their liability to active rheumatic manifestations, but these recurred with a return to New York. Parallel with these clinical variations ran a change in the bacterial content of the throat. This included haemolytic streptococci in New York which disappeared in Porto Rico, but came back again when the patients returned to New York. A somewhat similar series of observations demonstrated parallelism between the incidence of *Streptococcus haemolyticus* in the throat flora, and that of active rheumatic phenomena in children under treatment in a country convalescent home. Outbreaks of tonsillitis of the same kind have been noted by Schlesinger[2] at a similar home in Kent. Dr. Coburn alludes to this observation, and also to that of Hector[3] at a British fever hospital, which showed that "almost without exception an attack of scarlet fever in a rheumatic subject is followed by a reappearance of some of the symptoms associated with rheumatic infection." On these and other grounds he is disposed to regard the presence of haemolytic streptococci in the throat as having a close relation with the origin of rheumatic phenomena.

Inoculation of the skin with streptococcal filtrates has already been done by many workers in an endeavour to find a reaction, analogous to that of tuberculin, and of practical value in the diagnosis of rheumatic infection. Dr. Coburn's experiments were designed to test the existence of a relation between positive reactions and the presence of haemolytic streptococci in the pharyngeal flora. About 1,500 patients were tested, five different bacterial extracts being used. The patients with active rheumatic disease reacted positively to an extract of haemolytic streptococci with remarkable constancy, and in several instances the reaction assumed the characters of an erythema marginatum of the kind sometimes seen in juvenile rheumatism. Here Dr. Coburn's results have apparently been more convincing than those achieved by British workers, and he is entitled to claim that they support his views.

In the chapters that precede those summarized above the author gives an account of the observations that led him to search for the clue to the mystery in the flora of the upper respiratory tract. He noted that those environmental conditions which predisposed to "the rheumatic state" were also those in which infections of that tract flourished. It is thus that he explains the immunity of the Tropics from this disease. Certain it is that one of the outstanding facts of its causation is its limitation to the temperate zones, and in particular to the northern parts so far as Europe is concerned. Another striking fact is the influence of social position. This has been emphasized afresh by Dr. Reginald Miller, who, at a congress lately held in [illegible]ween the

high incidence of the disease among children attending the elementary schools and its almost complete absence from our great public schools.

In connexion with these problems there has been in this country a field research, the first of its kind, whose three years of investigation have now been completed. Large numbers of practitioners, medical officers of health, and school medical officers, reinforced by a group of consultants, have done their best to comb out every child with rheumatic heart disease in the three counties of Gloucester, Somerset, and Wiltshire. The interim report, based on 1,100 cases studied in this very arduous research, we have great pleasure in publishing at page 37 of the *Supplement*. The investigation, which is an outcome of the work of the British Medical Association's Subcommittee of Inquiry into Rheumatic Heart Disease in Children, is of particular value in that it deals especially with the prevalence of this condition in rural areas ; and about this we have had hitherto very little precise information. The report shows one very striking fact—namely, that in Bristol, the one great city in the area searched, the incidence of juvenile rheumatic heart disease was five or six times greater than in the surrounding rural areas. Whether or not this is to be regarded as confirmation of the view that industrialization is an important factor in the production of juvenile rheumatism, it agrees with the conviction expressed in Dr. Coburn's interesting book, that the incidence of the disease is particularly high in New York.

CHEMICAL NATURE OF ANTIGENS

An antigen is generally regarded as a substance which, on introduction into the living organism, leads to the development of a body or group of bodies capable of reacting in a more or less specific manner with the substance introduced. This reaction may be manifested in various ways, both inside and outside the body. For many years it was held that all true antigens were of protein nature, but the results of recent investigations have led to a modification of this conception. So much work has been carried out during the past decade on the chemical structure of antigens that we welcome the appearance of a monograph by Professor Oluf Thomsen of Copenhagen, summarizing the present position.[1]

Dealing first of all with the proteins, Professor Thomsen points out that not all proteins are antigenic. Gelatin, for example, is unable to give rise to the production of antibodies. There is evidence that this may depend on the poverty of aromatic groups in the molecule, gelatin being entirely deficient in tryptophane and tyrosine, and having only a small content of phenylalanine. Moreover, only those proteins which are foreign to the body of a particular animal can act as antigens. An exception must be made for the crystalline lens, which, on introduction into an animal of the same species, may yet lead to the development of specific antibodies. It is possible, however, to render a protein, naturally present in a given species of animal, antigenic to that animal by forcing upon it a new chemo-specificity. This can be done (as Obermayer and Pick, and Landsteiner have shown) by a process of iodization, nitration, or diazotization. Similarly, it has been found that under natural conditions the specificity of a given antigen may be determined, not by the protein molecule itself, but by a substance of carbohydrate nature which is linked to it. The specificity of the three common types of pneumococci, for example, is dependent on a difference in the carbohydrate substance which is combined with the basic pneumococcal protein. It is thus seen that an antigen may consist of at least two parts—one of which is " species specific," the other of which is " type specific." Further analysis has revealed the fact that the carbohydrate radicle, when entirely separated from the protein, may yet react specifically both *in vitro* and *in vivo* with the antibodies resulting from the injection of the whole antigen. The carbohydrate radicle, however, is by itself unable to give rise to the development of antibodies ; for this purpose it must be combined with the protein. The conception has therefore evolved of the existence of a substance, such as a carbohydrate, which possesses only some of the properties of an antigen ; such a substance is referred to as a " semi-antigen," or more frequently by Landsteiner's term, a " haptene." There is even evidence of a further class of bodies, referred to by Sachs as " semi-haptenes," which, though having no power to stimulate the production of antibodies or to combine with them *in vitro*, may be converted into haptenes by various substances which are able to bring about some change in their dispersion.

An antigen, it will be seen, is coming to be regarded as a mosaic, in which substances of non-protein nature may be responsible, in some instances at least, for its actual specificity. A study of the Forssman antigen, in particular, has also shown how the antigenic character of a protein may be altered by combination with a lipoid, acting as a haptene. Such an antigen may be artificially built up by combining the specific haptene—in this case the alcohol-soluble portion of the so-called F antigen—with an entirely different protein, such as ordinary hog serum. The injection of this complex into a suitable animal may give rise to the production of a haemolysin for sheep corpuscles in much the same way as the original Forssman antigen, which is present in aqueous suspensions of the lung or kidney of the guinea-pig, is capable of doing. The interest of these studies is by no means academic. Professor Thomsen discusses their bearing on such common clinical conditions as the idiosyncrasies. Many substances which are responsible for idiosyncrasy are not of protein nature. This fact has in the past often been regarded as proving the essentially different nature of idiosyncrasy and anaphylaxis. In the light of modern antigenic research, this proposition seems very doubtful ; and it is increasingly probable that some of the substances responsible for the idiosyncrasies are really of the nature of haptenes, which, by combination with certain proteins, are able to behave as antigens.

[1] *Antigens in the Light of Recent Investigations.* By Oluf Thomsen. Copenhagen: Levin and Munksgaard. 1931. (Pp. 187.)

VACCINATION OF MONKEYS WITH B.C.G.

Before advocating the widespread vaccination of infants with B.C.G., Professor Calmette, it may be remembered, decided to test the efficacy of his vaccine on monkeys. The actual experiments were carried out by Wilbert in New Guinea, and comprised tests on fifteen chimpanzees and fifty-six monkeys. All the controls became tuberculous, while of the vaccinated animals, though many died of intercurrent disease, none developed tuberculosis (see *British Medical Journal*, 1925, ii, and *Epitome*, para. 195, p. 34). Attempts to confirm Wilbert's work have proved, on the whole, unsuccessful. Tzechnovitzer, Schlossmann, Kirchner and Schneider, and Kalbfleisch and Nohlen, all failed to produce any significant degree of immunity in monkeys; in the experiments of Gerlach and Kraus some evidence of immunity was obtained, but the period of observation was limited to three months. In view of these discrepant results it is interesting to learn that the subject has again been studied, this time by no less competent and authoritative a worker than Dr. A. Stanley Griffith[1] of Cambridge. *Macacus rhesus* monkeys were used; twenty-nine were vaccinated, fifteen served as controls, and three were artificially infected for contact experiments. The vaccine was given by various routes, most commonly the mouth; sometimes single and sometimes multiple doses were given; the quantities of living B.C.G. bacilli administered were usually rather large, the total dosage by the mouth occasionally being as much as 1,000 mg. Immunity was tested for either by (*a*) instillation of small doses, 0.001 to 0.01 mg., of virulent bovine bacilli into the conjunctival sac, by (*b*) familial contact with infected monkeys, or by (*c*) subcutaneous inoculation with slightly attenuated bacilli. The interval between the last vaccination and exposure to infection varied, but was generally about one and a half to four months. All animals that died or were killed were carefully examined, and the type of the infecting bacillus was determined. In this way it proved possible to avoid confusion due to spontaneous infections, which were always due to the human type. The factors in the experiments were varied so much that no exact numerical comparisons are possible. The following results, however, seem to be fairly well established. When given by the mouth the B.C.G. strain, even in large doses, was found incapable of giving rise to progressive tuberculosis in monkeys. Intratracheal and intravenous inoculations, on the other hand, produced tuberculous pneumonia and even definite tubercles, though the lesions were limited to the lungs and did not tend to progress. Absorption of B.C.G. bacilli from the intestinal tract was found to occur to some extent, and the organisms could sometimes be recovered from the submaxillary or mesenteric glands, but Griffith believes that if they are to be absorbed in considerable numbers, which is presumably necessary for the production of immunity, the vaccine must be given over longer periods and in larger amounts than those recommended by Calmette. B.C.G. bacilli were found to remain alive in the lymphatic glands in some monkeys for periods up to six months without provoking characteristic tuberculous lesions, and without undergoing any increase in virulence for the guinea-pig. So far as the production of immunity was concerned, the results were almost completely negative. The vaccinated animals developed generalized progressive tuberculosis in much the same way as the control animals; the only perceptible difference was that in some of the vaccinated monkeys the disease was more protracted in its course and occasionally less in extent than in the controls. Whether in these instances the apparently higher degree of resistance was specific, resulting from B.C.G. vaccination, or was due to the greater age of the monkeys or variation in technical factors, could not be decided. If the former explanation is correct "it is evident," Dr. Griffith concludes, "that B.C.G. administered in the ways recommended by Calmette can produce, irregularly and inconstantly at most, only a low grade of relative immunity in the monkey."

[1] Griffith, A. Stanley: Studies of Protection against Tuberculosis. Results with B.C.G. Vaccine in Monkeys. Medical Research Council, Special Report Series, No. 159, 1931.

A HOUSE OF BOOKS

The rebuilt and enlarged premises of Messrs. H. K. Lewis and Co., Limited, medical publishers and booksellers, were the scene of a house warming on July 9th, when the directors entertained a large number of visitors, mostly members of the medical profession. Indeed, the company represented, as someone said, the life of a book, for there were authors, editors, publishers, printers, librarians, booksellers, and even, perhaps, in odd corners, readers! The new buildings have been designed to harmonize with University College, which they adjoin, and the dignified frontage at the corner of Gower Street and Gower Place bears a replica of the bust of Hippocrates presented by Messrs. Lewis some time ago for the Common Room of the British Medical Association House. The house of Lewis was founded by Henry King Lewis in 1844, not many years after the foundation of University College itself. Its first address was No. 136, Gower Street; No. 24, Gower Place was added in 1907, and now, through the co-operation of the firm with the college authorities, a worthy building has been added to Gower Street, for which that long, unlovely thoroughfare should be grateful. Sir Gregory Foster, until lately Provost of University College, who was principally concerned in the negotiations about the site and the building, presided over the brief commemorative proceedings, and said that his own memories of the firm went back for fifty years, to a time when it occupied a small shop of 25 ft. frontage, with a 240 sq. ft. floor space. Sir Gregory mentioned some names in the remarkable list of authors for whose books Messrs. Lewis had performed the office of obstetrician, and said how much he rejoiced in the success of a firm which had steadily pursued a high ideal. Professor H. R. Kenwood delivered a brief address on textbooks, surrounded as he was by shelves which were loaded with them. He pointed out the need for such books to be not only accurate in substance but interesting in style and stimulating to inquiry. As an old teacher he had long since come to the conclusion that no one properly knew his subject until he had written a textbook upon it. But a student, he added, should never restrict his reading to textbooks. He was inclined to doubt whether the standard of textbooks of recent years had improved to the same extent as their typographical production. They had assumed larger dimensions, but

some he had lately handled could have been much smaller without losing value. Professor Kenwood concluded with a word of warm congratulation to the hosts of the day. Mr. H. L. Jackson, a nephew of the founder of the firm, and one whose own association with Gower Street dates back for forty-three years, responded on behalf of himself and his fellow directors. He mentioned that one-third of the additional capital to finance the new venture had come from the staff, and a further considerable proportion from others whom it had been the firm's privilege to serve. The publication and distribution of medical and scientific literature presented peculiar difficulties, but there was always the joy to the bookseller of tracking down some perplexing query, and the publisher was consoled for his tribulations by his intimate contact with some interesting personalities. Mr. Jackson recalled that his own first meeting with Sir William Osler arose out of the disappearance at the printer's of a valuable piece of "copy"—a large tabular draft embodying an enormous amount of work, the only such occurrence in the long history of the firm. Fortunately, the distinguished author had a rough draft by him, and dismissed, in the kindliest way, a matter over which other men would have fumed. The proceedings ended with a few words of further congratulation by Dr. Percy Flemming, who mentioned the indebtedness of the medical profession to Messrs. Lewis and Co. for their circulating library, which had brought to many a poor student and medical man books he could not afford to purchase.

CONTRIBUTIONS TO THE STUDY OF CANCER

A number of Professor James Ewing's many friends and admirers have combined to do honour to him on the occasion of the sixty-fourth anniversary of his birth, by presenting him with a dedicatory volume or Festschrift on the subject of cancer.[1] In an appreciatory preface Professor W. H. Welch recapitulates the code of ethics to be observed in relation to a Festschrift, as laid down by Professor Morley. The principal conditions are that the dedicatee should be recognized as an international leader in his field of research, and that he should be an eminent trainer of scholars as well as himself an eminent scholar. The distinguished position occupied by Professor Ewing in these particulars will be admitted all the world over. It is sufficient to glance over the list of his papers, monographs, and textbooks, over a hundred and fifty of which are enumerated in the Festschrift, to realize his untiring devotion to the study of pathology and to the breadth of his interest in that science. Important as these contributions have been, it is, however, probable that his book on *Neoplastic Diseases* is that which has gained for him the greatest meed of appreciation, and has come to be considered as his chief contribution to science. As regards the scope of the Festschrift, Dr. Adair explains in his foreword that it is designed to include the most recent knowledge in the various subjects of cancer research, pathology, surgery, and radiotherapy from the scattered clinics and laboratories of Europe and America. It contains fifty-four articles under the general headings of cancer in its general relations, cancer research, regional cancer, and radium and Roentgen-ray therapy. A pleasing feature of the volume is a charming character study of Professor Ewing, sketched in chalk by Rebecca L. Taylor.

[1] *Cancer.* Comprising International Contributions to the Study of Cancer in Honor of James Ewing. Edited by Frank E. Adair, M.D., F.A.C.S. London: J. B. Lippincott Company. 1931. (45s. net.)

THE CREAM OF BEAUTY

Mr. Stanley Redgrove is doing his best to rend the veil of secrecy which has always been spread over the mysteries of the feminine toilette. In previous volumes he laid bare the secrets of the hairdresser, of the perfumer, and of the art of "make-up." He now provides a guide[1] to the manufacture, the use, and possibly the abuse, of a series of substances even more generally employed by women—namely, the very various preparations known as face creams. These are now almost universally used, and on the whole the results are gratifying. It is probable that the standard of female beauty is higher among the civilized populations of western Europe and America than it has ever been before, and, moreover, women are more successful in prolonging their period of beauty and charm into comparatively old age. This is due to a number of causes—better conditions of life, less drudgery, more intelligent feeding, and the general care and exercise of the body, to all of which the medical profession is proud to have contributed. But in addition some credit may be claimed by the chemists for providing various preparations for the preservation, and sometimes for the improvement, of the complexion. Of this subject, although it is full of medical interest, the profession has hitherto had very little knowledge. It is true that the first formula for cold cream was invented about eighteen hundred years ago by Galen, and with only slight modifications it is used even to this day, but since that time aids to the cultivation of beauty have been largely abandoned by the physician, and indeed he has rather frowned on the employment of creams and other artificial aids to adornment, implying that they do more harm than good. There may have been once some foundation for this prejudice, but the development of modern chemistry has provided a vast array of formulae for harmless and even beneficial creams which have now been introduced in one form or another into almost every civilized household. Mr. Redgrove professes in this little book to provide women with directions for the manufacture of these things in their own homes. We do not think that many of them are likely to take advantage of the opportunity he affords, but on the other hand he has given the medical profession in general, and the dermatologists in particular, valuable information on this subject in a convenient form, which they have long needed, and for which they should be duly grateful. There are, it appears, three principal categories of face creams—cold creams, vanishing creams, and emollient creams, and they have distinct functions. The cold cream, so called because the water incorporated in it causes a sensation of coolness when applied to the face, is properly employed only as a detergent. The function of vanishing cream, which is essentially an emulsion of stearic acid in water containing soap, is to provide a basis for the application of powder; while under the head of emollient creams

[1] *The Cream of Beauty.* By H. Stanley Redgrove, B.Sc., A.I.C. London: W. Heinemann (Medical Books) Ltd. 1931. (5s. net.)

are included all those which are applied to the skin at night in the hope of beautifying the complexion and remedying slight defects Many of these contain lanoline, which is almost the only substance easily absorbed by the skin, and lanoline creams are hence often known as "skin foods" We must refer the reader to the book for further details on these matters In addition to those on creams chapters will be found on face powder, rouge and lipsticks, toilet waters, and lotions On all of them the author is very knowledgeable, and his remarks are full of common sense and free from quackery On one point he is very reassuring —namely, in deprecating the common idea, almost amounting to a superstition, that the employment of emollient face creams may encourage the growth of superfluous hair He quotes scientific experiments to show that they have no such effect, and that any stimulation of hair growth is due entirely to increased blood supply to the hair follicles brought about by mechanical massage All medical men who are consulted from time to time by female patients about their complexions will find that an acquaintance with Mr Redgrove's little book will enable them to advise on this delicate subject with additional *savoir faire*

THE ORDER OF ST. JOHN AND THE BRITISH RED CROSS SOCIETY

The eleventh report of the Joint Council of the Order of St John of Jerusalem and the British Red Cross Society, which is summarized elsewhere in our columns this week, outlines the work of the various committees during the past year Perhaps the most outstanding achievement of the council since it was set up in 1920 has been the maintenance of a definite and enterprising policy during a period of rapid consolidation Not only has it exercised an exceptional vigilance in keeping abreast of progress in medical and technical knowledge, but it has shown a remarkable capacity for adapting its resources to the swiftly changing requirements of urban and rural conditions This power of adjustment to the emergencies of modern life demands an alert and co-operative spirit, and is well illustrated by the organization of elaborate services for dealing with accidents, and by the judicious establishment of over three hundred ambulance stations throughout the country Even more impressive than their material expansion is the fact that many of the services under the supervision of the council are staffed mainly by voluntary workers, who willingly surrender much of their leisure time, without thought of requital, in order to equip themselves for extremely arduous duties For example, it is not generally realized that the responsibility for the running, housing, and maintenance of the ambulance cars, the collection of subscriptions and weekly contributions, the arrangement of entertainments, and all the other methods employed to raise funds for their upkeep, is undertaken by voluntary workers, so that an efficient service may be available to patients by day and night, at little or no cost We hope that the council will continue to emphasize this important aspect of its work, for the social value of *disciplined* voluntary effort, intelligently directed towards the relief of physical and economic distress merits far more public consideration than it has hitherto obtained

"NUTRITION ABSTRACTS AND REVIEWS"

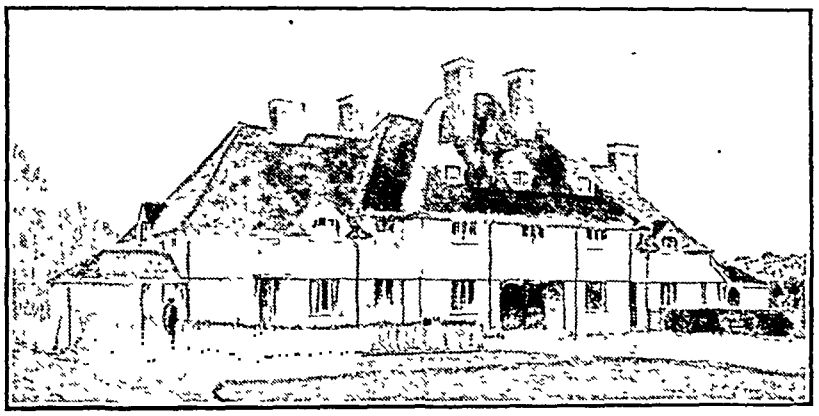
A new periodical—*Nutrition Abstracts and Reviews*—is about to be issued under the joint direction of the Imperial Agricultural Bureaux Council, the Medical Research Council, and the Reid Library, Aberdeen The editors are Dr John Boyd Orr, director of the Rowett Research Institute, and of the Imperial Bureau of Animal Nutrition, Aberdeen, Dr J J R Macleod, professor of physiology in the University of Aberdeen, and Dr Harriette Chick of the Lister Institute, London They will have the assistance of corresponding editors in other countries An attempt will be made in this journal to bring together abstracts of all papers which have a bearing on problems of nutrition, prepared, as far as possible, by workers actively engaged in research, it will also contain reviews by acknowledged authorities on the existing state of knowledge of particular subjects For the present it will be published quarterly, in January, April, July, and October, and the first issue —a double number—is due to appear in October next All communications should be addressed to the secretary to the Committee of Management, *Nutrition Abstracts and Reviews*, Imperial Bureau of Animal Nutrition, Reid Library, Rowett Institute, Aberdeen. The subscription is one guinea a volume, or 6s 6d a number (double numbers 13s), post free to any part of the world

ORTHODONTIC CONGRESS

The second International Orthodontic Congress will be held in London next week, from July 20th to 24th inclusive, under the presidency of Mr J H Badcock On Monday evening, after a presidential reception at the Savoy Hotel, Professor G Elliot Smith will give a popular lecture on evolutionary tendencies affecting both the teeth and the jaws On Tuesday evening the President and Council of the Royal College of Surgeons of England will hold a reception for members of the congress at Lincoln's Inn Fields, and on Thursday there will be a banquet at the Savoy Hotel The secretary-general is Mr B Maxwell Stephens, 76, Grosvenor Street, W 1 All meetings for papers and demonstrations will be held in the congress suite at the Savoy Hotel

THE ANNUAL MEETING AT EASTBOURNE

We published in the *Supplement* to our last issue the programmes of the Scientific Sections, and other details of the arrangements for the Annual Meeting of the British Medical Association to be held at Eastbourne next week It is very desirable that members attending the Meeting should immediately on arrival in Eastbourne register their names at the Reception Room, which will be in Devonshire Park



We regret to announce the death at Clifton Bristol, on July 12th, of Mr F Richardson Cross, LL D, F R C S, the veteran ophthalmologist

The annual general meeting of the West London Medico-Chirurgical Society will be held at the West London Hospital Hammersmith, to-day (Friday, July 17th), at 5 p m

THE BUCKSTON BROWNE SURGICAL RESEARCH FARM

FOUNDATION STONE CEREMONY

The foundation stone of the Buckston Browne Surgical Research Farm at Downe, near Farnborough, Kent, was laid by Lord Moynihan, President of the Royal College of Surgeons of England, on July 8th. The manner in which this great project has matured, the purchase of the Downe property through the liberality of Mr. George Buckston Browne, and the planning of this biological research station, were described in a leading article in the *Journal* of July 4th (p. 23). The stone which has been laid will form part of the porch of the large residential building, in the style of a Kentish farmhouse, which will house the research workers, as well as those in charge of the laboratories and the animals. The building of the animal houses and the experimental laboratories has not yet begun ; indeed, it is remarkable that so much progress has already been achieved, for Mr. Buckston Browne's benefaction was only made known to the College in the early part of the present year, and the site, which adjoins the Down House property, ever to be associated with Darwin, was selected only in March.

BUCKSTON BROWNE SURGICAL RESEARCH FARM, DOWNE, KENT

In addition to the President, the Vice-Presidents (Mr. C. H. Fagge and Mr. R. P. Rowlands) and most of the members of the Council journeyed to Downe. The President and Vice-Presidents wore their gowns, and the procession to the marquee was preceded by the College mace. A brief service of dedication was held by the Dean of Westminster, who, after Lord Moynihan had laid the stone in place, pronounced the words: "Here may knowledge be increased ; study fostered ; skill developed ; to the prevention and relief of suffering, the service of our fellow men, and the good of the human race throughout the world."

LORD MOYNIHAN'S ADDRESS

Lord MOYNIHAN addressed the company as follows: The Royal College of Surgeons of England to-day enters upon a new career. Hitherto it has fulfilled its statutory duties to the satisfaction of all. Henceforth it will assume fresh and wider responsibilities. Since Lister's day the main activities of surgeons have been directed to the recognition of disease in more and more precocious stages, and to the planning of methods of approach to and attack upon organs formerly inaccessible. Little by little it has become evident that no region of the body can stand aloof from our inquiry, that Lister has indeed given us a weapon which allows and even encourages us to find a path into territories which disease is able to enter. Surgery has become, then, not only the strongest of therapeutic measures, but also a method of research—a method by which, during the lifetime of the individual, the various stages and courses of disease can be investigated. Many new lessons have been learnt in that most procreant laboratory, the operation theatre, and while this has been proceeding, animal experimentation, the safety of which we also owe to Lister, has been widely carried on, with great benefit to the science and to the art of surgery.

The Council of the Royal College of Surgeons, which properly regards itself as the custodian of surgical advance in this country, has now recognized that for the further expansion of surgery there must be a correlation of the various results from methods of inquiry in three directions: (1) clinical research carried out in the wards and in the operation theatres of hospitals ; (2) biological and pathological research carried out also in hospitals and in special institutions ; and (3) research upon animals. In accordance with the Council's will, laboratories have been built and old laboratories extended in our buildings in Lincoln's Inn Fields ; there men have been set to work upon lines which they themselves desire, and there men have learned "the religion of research," and the high value of the experimental method in connexion with the science and art of surgery. Now, owing to the great beneficence of a Fellow of our College, we are here laying to-day the foundation stone of an institute for experimental research, which will add the one remaining event required for the proper development of surgery in this country.

Many memorials are raised to men, sometimes after their death, sometimes during their lives. Such memorials may be cast in bronze or graven in stone. Some are marked by a title, others by a decoration. But the finest memorials of all, we think, are raised up in the grateful hearts of men and women from whom a very heavy load of suffering and sorrow has been lifted. The finest memorial which can be raised to any man during his lifetime is surely an institute within which inquiry will take place resulting in permanent benefits conferred upon mankind. To-day we are recognizing the fact that Mr. Buckston Browne takes his place among those who may be regarded and honoured for all time as immortal benefactors. I will ask my old friend to say a few words of greeting.

SPEECH BY THE DONOR

Mr. BUCKSTON BROWNE said: Nature's discipline does not consist in a blow and a word. It does not consist even in a blow and a word some time afterwards. It consists in the blow without the word, and, as Professor Huxley told us years ago, it is for us to find out why our ears are boxed. When Jane Austen wished to pour contempt upon one of the creations of her wonderful brain, she said that he was a man without any curiosity. We who are here to-day recognize as our surgical patron saint John Hunter, who was a man devoured by an insatiable curiosity. I am sure that had John Hunter occupied the position in the Garden of Eden that Adam occupied, he would have taken a very large bite out of the apple. It is a very interesting fact that here we have been able to bring the great genius of John Hunter, who did so much for the alleviation of the suffering of the human body, alongside that great genius Charles Darwin, the emancipator—as I like to think of him—of the human mind. These two great men are brought together to-day on this really sacred spot in Kent.

Just one personal word. When I was a student I could not walk for ten minutes without meeting some unhappy

face scarred by small pox The mortality from small-pox in those days was terrible To day we hardly ever meet a pock marked face, and why? Because of the glorious work done by one of John Hunter s pupils, Edward Jenner—work done on a farm, a research farm as this is going to be With regard to myself and the too kind words which Lord Moynihan has spoken, I can only appear before you this afternoon as one of the most fortunate of men I have had a wonderful opportunity, and I am grateful to my College for it Under the aegis of that great and enthusiastic surgeon Lord Moynihan, and under the direction of my dear friend, that great anthropologist and biologist, Sir Arthur Keith—otherwise Lord Rector of the University of Aberdeen—I have been permitted to accomplish what I have done here I do believe, as Lord Moynihan has said, that we are entering upon an entirely new epoch in the history of our glorious old College

VISIT TO DOWN HOUSE

After tea had been taken, the company made their way along the sand walk—Darwin's 'thinking path"—to Down House, the property which was presented in 1927 by Mr Buckston Browne to the British Association as a memorial of Charles Darwin Here they gazed with interest at its steadily accumulating treasures, and especially at Darwin's study, kept as it was during his lifetime, with the little paraffin lamp on the table, and the dog (now a trophy of the art of the taxidermist) in its basket on the hearth

Others who accompanied the party, in addition to those already mentioned, were

Sir Thomas Barlow Sir James Berry Professor A H Burgess (Acting President British Medical Association) Mr McAdam Eccles Mr Victor Bonney Professor Graham Simpson Professor Hey Groves Mr Cecil P G Wakeley Dr Scott Williamson Sir Arthur Keith Professor Wingate Todd Professor Fraser Harris Dr de Bec Turtle Mr Sampson Handley Mr R C Hogarth Professor G E Gask, Dr John Eyre and Mr Winsbury White

ROYAL SOCIETY OF MEDICINE

ANNUAL MEETING

The annual meeting of the Royal Society of Medicine took place on July 7th, with the president, Dr T WATTS ELDER in the chair

The PRESIDENT in presenting the annual report of the council, said that the increase in the number of Fellows of the society was a matter of great satisfaction The present number of Fellows, excluding Honorary Fellows and members of other designations, was 4,160, an increase of nearly 600 upon the number five years ago On the other hand, the members of Sections (349) were decreasing, which showed that the advantages of full Fellowship were being more widely realized, so that new adherents became Fellows instead of merely sectional members The two new Sections of Physical Medicine and of Radiology (which had taken the place of the Sections of Electro Therapeutics and of Balneology and Climatology) were now fully constituted and members were enrolling in large numbers The old Sections themselves organized the change, and the matter had gone through very smoothly The society was indebted to the widow of a well known Fellow, Dr Edward Law, for a gift of £500 to commemorate her husband's work The money would be spent in the purchase of books for the library on otological, rhinological and laryngological subjects, in which Dr Law had been interested, and every book would contain a commemorative book plate

Professor WILLIAM BULLOCH one of the honorary librarians gave an account of the work of the library, which he said was now the second largest medical library in the world the largest being the Surgeon General's library at Washington Dr HUGH THURSFIELD, one of the honorary editors, spoke of improvements made and contemplated in the society's *Proceedings*

The report having been adopted, a ballot was taken for the election of unofficial members of council, 1931–32

The following were elected presidents of Sections (that is, vice presidents of the society) for the next session

Mr Ramsey Phillips (Anaesthetics) Mr Cecil Wakeley (Clinical) Dr J A Arkwright (Comparative Medicine) Dr A M H Gray (Dermatology) Sir Henry Gauvain (Disease in Children) Professor M Greenwood (Epidemiology and State Medicine), Dr R O Moon (History of Medicine), Mr W G Howarth (Laryngology) Dr H Morley Fletcher (Medicine) Dr Stanley Barnes (Neurology) Mr Victor Bonney (Obstetrics and Gynaecology), Mr E B Dowsett (Odontology) Mr E W Brewerton (Ophthalmology) Mr Harry Platt (Orthopaedics) Mr Norman Patterson (Otology) Professor E H Kettle (Pathology), Dr F G Thomson (Physical Medicine) Dr Bernard Hart (Psychiatry) Professor J M Woodburn Morison (Radiology) Mr C H Fagge (Surgery) Dr E P Poulton (Therapeutics and Pharmacology) Dr J Gordon Thomson (Tropical Diseases and Parasitology), Lieut Colonel E M Cowell (United Services) Mr Ralph Thompson (Urology)

On the motion of Dr DE BEC TURTLE seconded by Dr J D ROLLESTON, a hearty vote of thanks was accorded to Mr E K Martin, on his retirement from joint honorary secretaryship of the society after four years of devoted service in that capacity

Nova et Vetera

AN HISTORICAL ACCIDENT

The opening of the Manchester and Liverpool Railway in 1830 ended in a tragedy which has become of as much historical interest as the event which occasioned it—this was the death of Mr Huskisson The impression got abroad at the time, and has often been referred to since, that death was due to neglect through disagreement between the surgeons as to the proper treatment to adopt The following account of the event, taken from the *North of England Medical and Surgical Journal* 1830–31 (p 263), was written by Mr John Atkinson Pansome, F R C S, honorary surgeon to the Manchester Royal Infirmary, one of the surgeons called in to treat Mr. Huskisson

The Circumstances of the late Mr Huskisson's fatal Accident

The Right Honourable Mr Huskisson's melancholy case having excited, in a considerable degree the public sympathies, I am induced to avail myself of your respectable Journal, to state the particulars, as far as my observations extended Accompanied by Messrs Whatton, Garside and White, I was introduced to Mr Huskisson, at the vicarage, in Eccles, he was lying on a couch—his countenance was pallid—his expression was firm and collected, though he suffered from frequent spasmodic pains—his pulse thready and extremely feeble—his extremities cold, indicating the powerful shock his constitution had received, and which had not been succeeded by any reaction On inspecting the limb, the Tibia and Fibula were comminuted and the integuments much bruised and torn—the Os Femoris was broken into a great number of small, angular and rugged fragments—the Rectus and Triceps muscles were quite denuded and crushed, and the Sartorius torn across The sheath of the Femoral Artery was laid bare and the superficial nerves were exposed and torn The accident had occurred about two hours before we arrived Lord Wilton had, with great judgement applied a handkerchief and stick as a field Tourniquet which had restrained the hemorrhage The quantity which had escaped would not have been considered great had it occurred in a strong and vigorous man but in an individual sixty years of age, and previously enfeebled by disease and a recent operation, it was sufficient, in conjunction with the severe

shock occasioned by the accident, fatally to depress the vital powers.

Notwithstanding the premonition these alarming symptoms afforded, everything was prepared for amputation, but we discovered that the exhausted state of our patient rendered such a step highly improper. With the hope therefore of producing a favourable impression on the nervous system and thus rousing the vital powers, in order to enable him to bear the operation, cordials, viz. brandy, ammonia, and laudanum, were liberally administered—flannels, moist and hot, and sprinkled with laudanum, were applied to the limb, and bottles of hot water to the feet, and to the sides of the body. The femoral artery was secured, in order to prevent further haemorrhage. I lament to state, however, that these remedies were ineffectual, and that the fatal depression of the vital functions sensibly increased. After a short period, he complained of an extremely oppressive sensation at the praecordia—the pulse became imperceptible at the wrist—he suffered from a general sense of coldness; this was succeeded by rapid and laborious respiration, and, in nine hours from the period when the accident happened, he quietly breathed his last. During this period, no moment occurred that afforded a favourable opportunity for the operation, though our most anxious attention was directed to every symptom that could indicate it. Our patient gradually, but uniformly, declined and the succession of his symptoms was such only as rapidly conducted him to the deplored catastrophe.

Belgium

[FROM OUR OWN CORRESPONDENT]

A Standard for Specialists

Professor Coppez has made a most extensive study of a system of standardization relative to specialists in all branches of medicine. In his opinion it is essential that special certificates or diplomas of proficiency in each specialty should be granted. At present the official subjects recognized for such diplomas are surgery, paediatrics, ophthalmology, oto-rhino-laryngology, psychiatry, gynaecology, urology, physiotherapy, and certain manifestations of syphilis. To these there could be added with advantage the subjects of internal medicine, diseases of the nervous system, of the lungs, of the digestive system, and of the cardio-renal system. Professor Coppez holds that a candidate for the diploma should spend some time in an approved clinic, the requisite period varying according to the subject. As a result of the efforts of the Government and of the Belgian Medical Federation, committees of specialists have been appointed, consisting of professors in the university, of hospital directors, and of practitioners who have gained a high reputation in their particular specialty. A committee for each group is expected to arrange the medical services, to decide at which hospital the candidate will spend his period of instruction, to confirm certificates, to pronounce judgement on each candidate, and to draw up official lists of specialists, which will be kept for the benefit of public bodies and of various medical authorities. Doctors so qualified will be allowed to mention their specialty on their door plate, visiting cards, etc., and they alone will have the right to take part in the deliberations of scientific or clinical societies confined to their own subject.

Marriage of Syphilitics

In a statement with regard to the marriage of syphilitics Dr. Dujardin has expressed the opinion that the pre-marriage certificate is an indispensable social measure which ought to be legalized. He discusses the disease at length, stressing the fact that it is a secret one, easily concealed once it is discovered. Moreover, it frequently remains ignored by both sexes in its primary stages. The subsequent complications are well known. Dr. Dujardin deals with both acquired and hereditary syphilis, and with the marriage problems to which they give rise. The matter of hereditary syphilis, he maintains, can only be decided by a most exhaustive inquiry, conducted by the family doctor. In his view Friedmann's conclusions can be accepted as the essentials in giving advice to syphilitics who wish to marry. This authority states that if primary syphilis is treated within six days of infection a cure is possible in 80 per cent. of cases. At all other stages it is necessary to give four courses of novarseno-benzol, followed by supervision lasting two years at least, even though the disease is completely quiescent. Negative blood tests are also essential. These conclusions must not be regarded as absolute, and Dr. Dujardin says that the person affected should submit himself to an examination twice yearly. Syphilitic women, although they may have received a clear pre-marriage certificate, should be advised to have a course of treatment during each pregnancy.

Health of Native Labourers

A report by Dr. Trolli, principal medical officer of the Congo, contains some important observations on the question of the health of the native worker. Labour, he states, is difficult to procure, and there is naturally a shortage; housing, feeding, and transport constitute other thorny and intricate problems. Suitable natives must be selected for certain types of work, the greatest obstacles being found among the workers in the mining areas, on the railways, and in works of construction. The acclimatization of the native is an important matter, and the formation around the mills and staple industries of suitable industrial villages is essential. Overcrowding has to be avoided and, above all, the institution of compounds. Natives must be allowed time to get used to new conditions. Employers should strive to make the newcomer feel that he is in his own country surrounded by people of his own race; he should therefore be supplied with a diet resembling that of his own home. The work at first should be very light, as the native expends a tremendous energy, even though his output of work may be very small. A reference to the statistics of the Mining Union indicates that the mortality among experienced workers is 29.34 per 1,000, while among recruits it is as much as 76.99.

Overwork among School Children

Acting on a report by Dr. M. G. Rency on the subject of overwork among school children, a Franco-Belgian committee has passed several resolutions, one of which demands the representation of doctors on the councils of secondary education in Belgium. The meeting suggested that there should be a careful selection of special subjects, and that, above all, there should be no overlapping. The teachers should plan out a time-table and arrange suitable working hours. While it is agreed that home work cannot be discontinued completely, the recommendation is made that it should be spread evenly over the week.

Probationary Release of Mental Patients

A number of new rules governing the temporary discharge of mental patients have just been put into force. The doctor can allow, with the written consent of the appropriate authority, a mental patient to return home on probation. Records of patients so liberated will be kept by the medical officer of the asylum in a special register, and as soon as patients are sent home their names will be notified to the *procureur du roi*, as well as to the burgomaster of the district. Arrangements have been made whereby the discharge will become permanent after three months, unless the recovery is not complete,

in which case the time of parole may be extended for a further three months. In no circumstances can a period of more than a year be granted. If the patient is considered to be free from all mental disability he must return to the mental hospital, but only for a few days to allow certain legal formalities to be discharged.

Ireland

Evolution of Medical Services in Ireland

At the annual meeting of the North-East Ulster Division of the British Medical Association, held at Coleraine, Dr. D. Boylan delivered the presidential address, taking as his general subject the evolution of medical services in Ireland. Dr. Boylan said that he was no advocate of a State medical service, but as a student of the progress made towards such a service, from the introduction of the first State measure for medical relief to the latest legislation, he could not help foreseeing some such development. Ever since the introduction in 1765 of the County Infirmaries Act, the trend of legislation—he was, *of course, speaking of Ireland—had been towards extending* the scope of medical benefit to an ever-increasing proportion of the population. That measure was followed, fifty-three years later, by "the Act to establish fever hospitals and to make other regulations for the relief of the suffering poor, and for preventing the increase of infectious fevers in Ireland." This Act provided that in any county, town, or district where voluntary subscribers formed themselves into a committee for providing medical attendance for the poor, they could obtain from the grand jury of the county a sum equivalent to that subscribed. Dr. Boylan sketched the history of such a committee in the Province of Ulster, and mentioned some points of interest in the annual reports of the medical officers. After the Hospitals Act came the Poor Relief Act, 1838, which established workhouses and boards of guardians; then, under the Medical Charities Act, 1851, boards of guardians were enabled to divide the unions into dispensary districts and appoint committees of management for the dispensaries. The regulations drawn up by the commissions of inquiry which had preceded that Act were still in existence in Ireland. The Public Health Act, 1878, provided for the specialist treatment of poor people through the agency of the local public health authority; the Local Government Board Act, 1898, extended the benefits of infirmary treatment to persons other than the poor; and then came the Insurance Act, 1912, followed in 1930 by the Act of the Parliament of Northern Ireland for the extension of medical benefits to insured persons. Provision was now made by the State for the medical treatment of at least half the population—in his own district, for more than half—and the next step would be free school clinics for dental, ophthalmic, and other treatment. Dr. Boylan believed that the day would come when the public would demand diagnosis and treatment as far as possible by specialists. Private practitioners would disappear, and all would be members of a State service. The general practitioner would be a clearance officer, to direct the patient to the appropriate special clinic. This would mean less interesting work, but those who remained in general practice would do so by their own choice. The country would be divided into districts, similar to parliamentary constituencies, in each of which there would be a headquarters hospital, with a full staff of specialists, and district hospitals, with a smaller and more junior staff. Districts corresponding to the present dispensary areas would be adequately staffed by general practitioners, who would attend to minor ailments. Dentists, chemists, and nurses would be absorbed in the State service. After pointing out that the financial aspects of the scheme were outside the limits of his address, Dr. Boylan closed with a word of reassurance, that before such a service came into being the youngest of those present was likely to be in enjoyment of the rewards *which he doubtless so richly deserved.*

Professor Ariens Kappers

During a recent visit to Ireland to receive the honorary degree of D.Sc. from the University of Dublin, Professor Ariens Kappers, director of the Central Institute for Brain Research, Amsterdam, delivered three lectures on the subjects with which his name has been associated as an original investigator during the past decade. The first, delivered before the Royal Academy of Medicine, dealt with the significance of the sulci of the brain, and with the importance of the surface form of the brain in man and animals. Special stress was laid on the relationship between brain weight and body weight, and on the fact that complexity of brain surface depended to a large extent on the number of the skilled movements which could be executed by the possessor of the brain. Domesticity, it was pointed out, diminished complexity. In the *second lecture, on the phylogeny of the neuroglia and of* the cerebro-spinal cavities, delivered before the Association of Neurological Surgeons, it was mentioned that the foramen of Magendie is purely an artefact. The third lecture, on the function of the various cellular layers of the cortex, was given to the Royal Medico-Psychological Association, which held its annual meeting in Dublin from July 7th to 11th. This address, which was of a very technical nature, was delivered to neuropathologists, and was profusely illustrated by lantern slides. Comparison between animals and man showed that one part of the brain (the supragranular cortex) developed at the expense of another as the cerebrum became organized. In the higher monkeys, such as the chimpanzee, there was a greater development of the supragranular cortex than in the lower orders of monkeys. In the cat the supragranular cortex of the brain was less developed than in the tiger, an animal much larger in *size, but nearly related. Professor Kappers also discussed* some of the diseases of the brain, and showed, by means of lantern slides, that it was the supragranular cortex that became affected. At the conclusion of the lecture Dr. R. R. Leeper, president of the association, said that it was a great privilege even to see such a man as Professor Kappers, and to sit and listen to him was an outstanding honour that they would always remember. Professor J. Shaw Bolton, who seconded the vote of thanks, paid tribute to what he described as a remarkable address.

Medical Inspection of School Children (County Down)

In the course of his report to the regional committee, Dr. John Scott, chief school medical officer, County Down, emphasized the necessity for the teaching of hygiene in public elementary schools. At present the subject was usually given an insignificant place, with results that were apparent even on a casual inspection. During the past year the question of providing a midday meal to children considered by the medical officers to be suffering from malnutrition was under consideration. The great majority of these children were normally resident in Newry, where apparently there was an abnormal amount of hardship arising from widespread unemployment. It had been decided by the regional committee to provide a midday meal to all such children attending the Newry public elementary schools, and coming from homes where the weekly income, after deduction of the house rent, did not exceed 3s. 6d. per person. The hope was expressed that all arrangements in connexion with the cooking [illegible]

distribution of these meals would be completed in time to enable this service to be started on November 1st. With regard to the treatment of eye defects, Dr. Scott stated that in his opinion three main factors were responsible for the failure of parents to see that visual errors in their children were corrected—namely, high cost of spectacles, lack of facilities, and children's dislike of wearing glasses. Last year parents were invited to attend the medical inspections of their children. In many schools the response was overwhelming; in some urban schools over 90 per cent. attended. Such a high percentage of parental attendance was not general, however, and in many small country schools less than 5 per cent. put in an appearance. Almost invariably the parents had expressed themselves grateful for the opportunity, and had voluntarily promised that the advice given would be followed.

Scotland

Sanitary Institute Congress

The forty-second congress of the Royal Sanitary Institute, held last week in Glasgow, was attended by over 1,000 delegates; in addition, there were representatives from some 580 local authorities throughout the Empire, as well as from foreign countries. In his inaugural address Sir Henry Mechan dealt particularly with the health of the worker, and the development of the measures that had produced the present standard. In light occupations, he said, monotony was now relieved by the introduction of a short rest, tea being given in the morning spell of work; where the occupation was laborious leave to smoke was often permitted at a stated hour without stopping of medicines. Various welfare schemes had been adopted by employers of labour and supported by the good will of workers, and these expressed a united aspiration towards a new social ideal. It had been suggested by the Registrar-General that a mortality rate for male occupations, based on the deaths of the men, but on those of their wives, would throw an important light on home influences as a factor in industrial health. It was generally realized that the present conditions of sanitary surroundings often reacted strongly on the health of the worker, and he believed that the recent amelioration of the worker's condition must be ascribed, in part, to the clinic, civic progress.

On the second day of the conference, Dr. J. Parlane Kinloch, chief medical officer of the Department of Health Scotland, delivered an address on "The health services modern State." He claimed that the present battle for a clean environment had a minimum against destitution might have to be regarded as a further effort was necessary to confirm tendency to abandon the old form of which embodied the worst features of

In a statement with regard to the coal before atmospheric smoke pollu- Dr. Dujardin has expressed the opinion that a large number of services had been marriage certificate a reduction of disease and the mitigation which ought to be among these, maternity service, child length, stressing the health service, and a national health concealed once service had grown from the elementary consideration that an adequate health service must be concerned with the care of the individual. The policy now in practice was that good nurture should obviate the need for treatment. An important question was the assessment of fitness of the individual. Some connexion must be established between the national health insurance service and the hospital services, to enable the practitioner to have all the facilities he needed for specialist diagnosis and treatment. Finally, there must be an intensified effort to extend the boundaries of present medical knowledge, for such bodies as the Medical Research Council, the Industrial Health Research Board, and the Empire Marketing Board had demonstrated that expenditure on research returned remarkably good dividends. In opening a discussion on "The role of the voluntary general hospital in preventive medicine," Sir Humphry Rolleston briefly sketched the history of voluntary hospitals, while Dr. Ralph Picken, medical officer of health for Cardiff, expressed the opinion that the greatest contribution the council hospitals could make to prevention was the provision of opportunities for teaching and research. Sir David Munro, secretary of the Industrial Health Research Board, said that the war had brought out the need for more systematic study of the optimum hours and the environmental conditions that were necessary for the worker to produce the maximum output. A recent survey of the physique of women had enabled conclusions to be drawn concerning the relationship of physique to the type of work to be performed, and in particular regarding the optimum weights to be handled and carried. A similar research was being carried out on the physique of men. These investigations were typical inquiries in a large field which had not yet been explored; for example, the influence exercised by design of machinery and appliances on the working capacity of the operator has still to be determined.

On the third day Professor E. P. Cathcart gave an address to the Section on hygiene of food, in which he said that a proportion of the population was inadequately fed. This was not due so much to inadequate income as to bad buying and bad cooking. Little could be done by the wholesale distribution of leaflets supplying simple nutritious menus, for the recipients seldom had the skill or the cooking utensils to make use of the advice. Cooking classes at schools seldom tried to visualize home conditions, and it would be an advantage if courses were given on the basis of using one pan and one small gas ring. The hygienic principles of bread-making were outlined by Professor David Ellis of Glasgow Royal Technical College. Bread, he said, was one of the safest articles of diet, because the loaf proclaimed its own deficiencies, and there was no method of doctoring a bad loaf. Further, the chances of disease being contracted through the handling of the loaf in transit to the customer were too remote to be considered seriously. In a discussion on various types of hospitals Dr. Samuel J. Cameron of the Royal Maternity Hospital, Glasgow, said that maternity hospitals had a great responsibility in regard to preventive medicine. He believed that the establishment of several small maternity hospitals throughout a city or county was a wasteful expenditure; for such small institutions, besides being costly to maintain, were inadequately equipped to deal with grave emergencies. A better plan was to open ante-natal clinics where normal cases could be separated from abnormal, and the latter drafted to a large central hospital for treatment. In opening a discussion on the housing question, Lieut-Colonel William Butler estimated that the present shortage of houses was roughly equivalent to the accumulated population, for some 2,000,000 possible emigrants would, at the pre-war rate of emigration, have been housed over-seas, but had been retained in this country.

Changed conditions of work and intolerance of meagre accommodation had also contributed to increase the demands for housing accommodation Mr Alan W Ritchie, chief sanitary inspector, Edinburgh, pointed out that the problem of slum clearance in the North differed from that in the South In Scotland the tenement system predominated, and the main causes of squalid conditions were serious site congestion, subdivision, and the lack of necessary sanitary conveniences This problem was one of the unhappy consequences of the industrial revolution, and although the first errors in town planning and house construction should not be blamed too strongly, their repetition by subsequent generations was rightly a matter of astonishment These mistakes were being rectified more quickly in Scotland than in England, although the population of Scotland was about one eighth that of England there had been thirty nine slum clearance schemes by local authorities in Scotland, involving 17,000 houses and 70,000 persons, while the English schemes had involved only the demolition of about 15,000 buildings and the re housing of some 74,000 persons The need for slum clearance and the provision of new houses was urgent everywhere

On the fourth day the question of a general medical service for the nation was reviewed by Dr Thomas Gibson, medical officer for Wakefield, who pointed out that the main proposal in the scheme offered by the British Medical Association was to extend the National Health Insurance Act so as to include the dependants of all persons already insured, and, by suitable arrangements, to include indigent persons as well, so that a complete medical service should be developed for all workers and those whose income did not exceed £250 per annum He thought that this proposal would achieve an enormous improvement in the medical care of the population Mr John Wilson, chief architect, Department of Health for Scotland, speaking on hospital planning, said that there were certain differences between the ideals of hospital construction in this and in other countries In this country they had concentrated chiefly upon sanitary details, on cleanliness, on the Continent, and particularly in Germany, the treatment of the surroundings, by the provision of greater space round ward blocks, was much superior to that prevailing here In Europe generally, single or two storey buildings still held their own, and possibly in matters of hygiene and sanitation the hospitals of this country were better than those in America or Europe Referring to legal regulations for the disposal of condemned foodstuffs, Dr Gerald Leighton, medical officer to the Department of Health for Scotland, said that it was of great importance for the safety of the public health that there should be no possibility of condemned foodstuffs ever reaching the public in the shape of food Theoretically, at least, this risk existed in the absence of any definite control by the local authorities or by legislation He thought that the disposal of condemned foodstuffs of all sorts should be carried out by the local authorities under a definite system of local regulations, and that it should not be possible for such material to be handed over to irresponsible persons In regard to bovine tuberculosis Mr Arthur Gofton, chief veterinary inspector, Edinburgh, expressed doubts in regard to the efficiency of pasteurization He admitted that the process did very materially reduce the amount of tuberculous milk which would otherwise reach the public but he considered that through failure of the Local Authority or through development of faults in plant, commercial pasteurization was not so efficient as was generally supposed and much greater supervision was necessary in this country A health exhibition was held in the McLellan Galleries during the sitting of the congress

Health of Scotland

According to the return of the Registrar General for Scotland dealing with the quarter ended March 31st, the number of births—namely, 23,558—was 471 more than in the preceding quarter, but 908 below the average of the first quarters of the preceding five years The general birth rate was 19·7 per 1,000 of the population, made up of a rate of 20·7 for the large burghs and 18·6 for the rest of Scotland In individual areas the rates ranged from 31·9 in Port Glasgow and 27·0 in Hamilton to 16·2 in Edinburgh, 12·7 in Shetland, and 13·9 in Sutherland. The deaths registered during the quarter numbered 20,189, being 4,204 above those recorded in the previous quarter. This gave a death rate of 16·9 per 1,000, which was 3·8 above that for the previous quarter The number and rate per 1,000 were, however, 250 and 0·2 below the average for the corresponding quarter of the last five years The death rate in the large burghs was 17·3, compared with 16·5 for the rest of Scotland The death rates ranged from 21·6 in Arbroath to 10·0 in Clydebank The number of deaths for each of the three months in the quarter were January 6,666, February 6,145, and March 7,378 In regard to infantile mortality, the deaths of children under 1 year numbered 2,653, representing a rate of 113 per 1,000 registered births Although these figures are higher than in the last quarter, they are much the same as the average for the first quarters of the preceding five years The rate of infantile mortality, which was 117 for the large burghs as compared with 106 for the rest of Scotland, varied from 158 in Coatbridge to 48 in Falkirk, and, as regards counties, from 206 in Nairn to 28 in Inverness Out of the 20,189 deaths registered, 1,605, or 7·9 per cent, were due to the principal epidemic diseases, including 56 from measles, 41 from scarlet fever, 438 from whooping cough, 118 from diphtheria 764 from influenza, and 90 from cerebro spinal fever Deaths from all forms of tuberculosis were 1,202, or 6 per cent of the total deaths Malignant disease accounted for 1,828, or 9·1 per cent of all deaths Deaths from pneumonia numbered 2,144, and from bronchitis 1,758 These two diseases accounted respectively for 10·6 and 8·7 of the total deaths Diseases and accidents of pregnancy and childbirth caused 156 deaths, equivalent to a rate of 6·6 per 1,000 births This rate, however, was 0·8 lower than the average rate for the corresponding quarters of the preceding five years

Veterinary Teaching in Edinburgh

The annual distribution of prizes of the Royal (Dick) Veterinary College, Edinburgh, was held on July 3rd, under the presidency of Professor Sir T Hudson Beare, who said that there was a great demand by the farming community for veterinary surgeons Only in institutions like that college could they cope with the tremendous loss produced by sickness of animals, such as the present outbreak of foot and mouth disease Expansion of the college had now become necessary, for the hospital was not large enough, and there was not sufficient room for advanced teaching He therefore desired to make an appeal to the whole of Scotland for funds It would be necessary to collect about £30,000 to complete the scheme at present in view Referring to the Lovat scheme Principal O C Bradley said that a number of colonial veterinary scholars had been elected during the past session, with the aim of recruiting suitable men for the colonial veterinary service In association with this scheme a diploma in veterinary State medicine had been instituted by the University of Edinburgh The prizes were presented by Sir Norman Walker, President of the Royal College of Physicians, who commented on the remarkable progress in human and veterinary medicine that had occurred in the past fifty years The successful

result of the war had been due partly to the success of the doctors in suppressing typhoid fever, and of the veterinary surgeons in suppressing glanders. Various common diseases of great importance called for the collaboration of the two professions; many of the subjects studied by medical and veterinary students were the same, even though they might differ in detail. Thus the linking up of the Veterinary College with the University was a great advance.

England and Wales

Conference on a National Maternity Scheme

The programme of meetings in connexion with the jubilee of the Midwives' Institute (*Journal*, July 11th, p. 73) ended with a conference at which the position of the midwife under a national maternity scheme was discussed. Dr. William Paterson, chairman of the Maternity and Child Welfare Subcommittee, dealt with the relationship of the midwife to the general practitioner under such a scheme; Mr. Treherne West, with her relationship to the Insurance Committee; and Dr. R. A. Lyster, with her relationship to the Central Midwives Board and the local authority. Dr. Paterson gave a concise exposition of the British Medical Association's memorandum, approved by the Representative Body in 1929, as a contribution towards the establishment of a national maternity scheme, and then submitted himself to catechism. The first question asked was with regard to the statement that up to the time of confinement ten visits might be paid by the midwife to the pregnant woman. Suppose after the tenth visit the woman went into hospital, was the midwife to be remunerated? Dr. Paterson replied that it was certainly the view of the Association that the midwife should be compensated for her ante-natal work. Another speaker was of the strong opinion that no midwife should ask a patient at the beginning of the ante-natal examinations which practitioner she would like called in in case of necessity. The mention of a doctor to many women, said this lady, conveyed the suggestion of forceps, and put the fear of maternity into their hearts. Dr. Paterson replied that the reason for the question was not to frighten but to reassure the patient; of course, it was for the midwife to exercise discretion and tact, and perhaps the question might be postponed to a second or later visit. A midwife said that midwives generally received post-certificate instruction. What did the British Medical Association propose with regard to refresher courses for practitioners? She spoke in derogatory terms of the competence of young doctors in obstetrics. Dr. Paterson replied that the education of the modern practitioner in obstetrics had greatly improved, a statement which was received with cries of dissent. At any rate, he had come across many young doctors lately whose sound knowledge had surprised and gratified him. Another midwife said that it appeared to her that under the scheme midwives were likely to pass—as indeed they were now passing—into maternity nurses. Once the woman got inside the surgery, she became in many cases the practitioner's patient, the midwife becoming a maternity nurse, or being dropped in favour of a handy-woman, because the patient could not afford the midwife's fee as well as the doctor's. Dr. Paterson pointed out that under the scheme, if the doctor was going to take the case, he would have to explain to the local authority why this was necessary, and if it was a normal case he could not take it. Another speaker strongly urged that the British Medical Association should act towards the medical student as the Central Midwives Board did towards the midwife, and see that every young doctor went into practice with a good experience of midwifery. The midwives were the "consumers" of the service of the doctors in this respect, and as consumers had every right to criticize its quality. Dr. Paterson pointed out that the British Medical Association did not control the education of doctors; that was the function of the General Medical Council, which had for years been pressing on the schools the necessity for better training in obstetrics, and he thought the position had greatly improved, and would improve yet more. Further, under the scheme, the general practitioner, who was formerly alone, would be able to call in specialists and anaesthetists, and to have ambulance facilities and hospital beds. Miss Edith Pye, president of the Institute, said that it was gratifying to have the express recognition by the British Medical Association of the fact that maternity was a normal process, of which the midwife was properly in charge. The Institute had generally accepted the view that there should be an examination of the pregnant woman by a doctor, on the ground that two heads were better than one, and that this course was a safeguard for the midwife as well as for the prospective mother. The midwives as a whole had a very warm and sincere desire to co-operate with the medical profession.

The Order of St. John and the British Red Cross Society

The eleventh report of the Joint Council of the Order of St. John of Jerusalem and the British Red Cross Society, covering the period from January 1st to December 31st, 1930, records that the total number of patients assisted since the beginning of the war by the auxiliary hospitals for officers department is 18,125—an increase of 97 during the twelve months under review. Although the main work of the department consists at present in helping tuberculous ex-officers, assistance is also given to surgical, medical, and convalescent patients, by admitting them for treatment to the Officers' Hospital at Brighton. This institution, which works in close co-operation with the Ministry of Pensions, received 97 in-patients in the course of the year. Among the services rendered by the department, aided in many cases by the Officers' Association, were refunds of hospital stoppages, payment of full sanatorium fees, and the payment of travelling expenses for officers sent to Switzerland, Italy, and the Riviera for treatment. In the previous report reference was made to the central bureau of hospital information, instituted in 1928 under the auspices of the Joint Council and the British Hospitals Association. This organization, which now includes the information bureau of the Incorporated Association of Hospital Officers, aims: (*a*) to publish annually a hospitals year-book containing a directory of hospitals in Great Britain, along with a report giving details of their work, finances, etc.; (*b*) to collect and summarize data of interest to those engaged in hospital management and in the direction of hospital policy; (*c*) to establish a library where books, pamphlets, and diagrams concerning matters of hospital administration, construction, and equipment may be consulted; and (*d*) to act as a clearing-house of information. It is impossible to give here any adequate idea of the bureau's intelligence service, but an indication of the variety of topics dealt with is furnished by the present report, which contains an abridged list of about sixty subjects on which information has already been supplied. The services of the bureau may be used without additional charge by all hospitals which are members of the British Hospitals Association. During the year the bureau has continued the publication

of its hospital memorandums, and has undertaken the preparation of the first edition of the new year-book, which is based partly on *Burdett's Hospitals and Charities*, and has been designed to provide a comprehensive and up-to-date survey of every department of hospital work. The rest of the council's report is occupied mainly by a review of the philanthropic services organized by the various committees—the Comforts and Wards Industries Committee, the Drives and Entertainments Fund, and the Emergency Help Committee, which has provided assistance during 1930 in over 13,000 additional cases of sickness and disablement among ex-service men and their dependants. This committee's report is of special interest, as it includes a historical note on the organization of its services since it was set up in 1920. The Home Service Ambulance Committee records that 325 ambulance stations have been established in the country, and that over 111,000 patients were carried in the course of the twelve months. Despite a considerable saving in administrative expenses, the financial statement for the year reveals a deficit on ordinary income of £1,751. The council explains that this is partly due to the realization of securities to meet capital outlay on Joint Council House, and partly to a decline in other sources of income.

Woodside Nerve Hospital

The Earl of Athlone, K.G., on his return from South Africa, consented to accept the position of president of the ancient Foundation of St. Luke's Hospital, and consequently of the Woodside Nerve Hospital, upon which the activities of St. Luke's are for the present mainly concentrated. On June 30th he visited the Woodside Nerve Hospital, which was opened in November last for the reception of cases of functional nervous disorder.[1] He was received by the treasurer (Lord Blanesburgh), the committee of governors, and such of the honorary consulting staff as were able to be present. The celebrations at the Leeds University, however, prevented several of them being present, including Sir John Bland-Sutton, Sir John Rose Bradford, Sir Farquhar Buzzard, Lord Dawson, and Sir Humphry Rolleston. The hospital stands in some six and three-quarter acres of ground overlooking Highgate Woods, and has accommodation for fifty patients—twenty men and thirty women. The majority of the rooms in the ward blocks are single bedrooms, and all of them face south, each one opening on to a broad veranda. There are also some private sitting rooms. The treatment block contains rooms for hydrotherapy, colon lavage, massage, light and electrical treatments. There are also in this block dental and *x*-ray rooms, photographic dark room, dispensary, and large laboratories equipped for investigation and research. All the capital expenditure in building and equipping has been borne by the St. Luke's Hospital Foundation, but the resources of this Foundation are unequal to the heavy cost of maintaining the new hospital. This cost must therefore be borne to a great extent by the payments of patients according to their means. At the present time a minimum charge of 5½ guineas a week is made on each bed, 2 guineas extra being charged for a single room. At the same time, every effort is made by means of rebates on these charges, allowed at the discretion of the committee, to make the resources of the hospital available for those of limited means. These fees are inclusive of all necessary forms of treatment, the only extras charged being for personal laundry, special nurses, and such personal comforts as are not generally included in treatment. During the six months that the hospital has been opened sixty-five patients have been admitted, and the majority of those discharged have gone out recovered.

Correspondence

DIVERTICULA OF THE COLON

SIR,—I was interested to read Dr. Edmund Spriggs's comments in your issue of July 4th on the paper by Dr. Graham Hodgson and myself, published in the *Journal* of March 28th (p. 525).

Dr. Spriggs's chief argument is that the evidence which we put forward in our paper to show that there is no inflammatory prediverticular stage is not a complete proof of our conclusions. While one must admit that it would be more satisfactory if we could show the histological appearances of a portion of bowel wall previously identified by *x* rays as showing his so-called prediverticular stage, at the same time we have got much better evidence against the inflammatory prediverticular stage than he has for it. The whole of the evidence for the presence of an inflammatory prediverticular stage he has produced so far is the *x*-ray appearances of the bowel wall, a proverbially unsatisfactory form, and quite unsupported by any histological findings. I maintain we have shown histologically that the very earliest condition of microscopical diverticula occurs in the bowel wall unaccompanied by any signs of inflammation, that the *x*-ray appearances which Dr. Spriggs has ascribed to inflammation of the colon wall are much more reasonably attributable to this condition of minute diverticula, and that it is not necessary to assume that an inflammatory condition of the bowel is the cause of the *x*-ray appearances.

The onus of proving that diverticula of the colon follow on previous inflammation is upon Dr. Spriggs. So far he has only produced *x*-ray photographs in support of his contention, and we have shown that these appearances are capable of a different interpretation. I agree with him that further knowledge of the earliest stages in the production of diverticula of the colon is wanted, but such knowledge is difficult to obtain, and is only found more or less by accident. While in no way wishing to belittle the very valuable work done on this subject by Dr. Spriggs and his associates, I submit that it is obvious that *x*-ray evidence is not at all satisfactory, and that the surgeon who sees and handles the colon during the course of operations on the human subject has a better opportunity of observing the early stages of the condition. Occasionally as the result of examining colons in the pathological department an opportunity is presented of actually obtaining sections of the bowel wall in the earliest stages of the condition; this evidence seems to me to be the most convincing.

I cannot follow Dr. Spriggs's argument that if the condition is due to pulsion pouches there should be a steady progression of the condition over a series of years. No diseases progress regularly; there are always periods of quiescence and others of progress. I much doubt if any case of diverticula formation ever does other than progress, and, although the condition may be made to stand still by suitable treatment, I have never seen any evidence that an actual regression in the condition has taken place, either as the result of treatment or otherwise. At the end of his letter Dr. Spriggs estimates the risk of perforation in cases of uncomplicated diverticulosis as about 1 per cent., a figure with which on the present available evidence I should agree. But in our paper we were referring to the risk of perforation in cases of diverticulitis—that is to say, where secondary inflammatory complications have already occurred—and that is quite a different matter, as perforation is quite a common complication in diverticulitis. I have personally never operated on an uncomplicated case of diverticulosis for that condition, but I have often operated on cases of diverticulitis, and

am much impressed by the advisability of this being done before, and not after, serious complications have occurred. Too often one has to try to remedy an almost hopeless condition of sepsis and adhesions when an operation at the right time would have prevented the danger. The surgeon is too frequently called in to deal with end-results instead of being allowed to prevent them.—I am, etc.,

J. P. LOCKHART-MUMMERY, F.R.C.S.

London, W.2, July 10th.

AFTER-EFFECTS OF IRRADIATION OF UTERUS

SIR,—In your issue of June 13th (p. 1045) Mr. Malcolm Donaldson makes an interesting speculation on the possible prophylactic value of radium against carcinoma of the cervix, with reference to which the experience at this hospital in the treatment of uterine haemorrhage may be of interest. When irradiation of the uterus was started in 1921 it was thought possible that the treatment might be followed by malignant changes in the uterus, and we have therefore watched our cases for this sequel, following them up persistently in the same way as cases of malignant disease.

Of 266 cases treated since 1921, of which 107 have been followed up five years or more, and 19 only are untraced, no case of carcinoma of the cervix or body supervening on irradiation has come to our notice. One case, however, of carcinoma of the ovary which occurred recently is of interest in that it suggests an effect of irradiation the reverse of that contemplated by Mr. Donaldson.

A. M., aged 42, was treated in November, 1929, for menorrhagia. At operation the uterus was found to be bulky and to contain several fibroids. There was no palpable abnormality of the appendages. The treatment was cavitary irradiation of the uterus with two tubes of 25 mg. radium element screened with 0.5 mm. of platinum and 2.1 mm. of silver for sixty hours, that is 3,000 mg. hours. In January, 1930, the patient was readmitted and was found to have a large ovarian tumour, for which hysterectomy and bilateral salpingo-oöphorectomy was performed. The tumour was a malignant ovarian cyst 7 inches in diameter, and there were numerous metastases in the peritoneum. Lead treatment was given, but failed to arrest the metastases, and the patient was moribund when last heard of in December, 1930. I am indebted to Mr. Clifford White for permission to report this case.

A similar result following *x*-ray treatment of a patient with fibroids has been reported by J. L. Faure (abstract in *Cancer Review*, vol. vi, No. 2), who cites other cases as showing ill-effects of irradiation upon ovarian cysts.—I am, etc.,

R. S. PILCHER,
Radium Registrar, University College Hospital.

London, July 9th.

AFTER-HISTORY OF PATIENTS WHO SUFFER FROM DYSPEPSIA IN INFANCY

SIR,—The question is not infrequently asked, "Does the child who has been subject to dyspepsia or marasmus during infancy suffer from indigestion during adolescence and adult life?" As a matter of fact the answer is not easy, for in the vast majority of cases one loses sight of those little patients who have caused us so much anxiety during the first few months of life. It so happens that I am able to give details of one case, which should prove of interest.

Over twenty years ago I saw a little girl, aged 6 weeks, who suffered severely from dyspepsia, followed by marasmus. She was treated first with white wine whey, then rennet whey, and later on by percentage feeding. (This is the very type of case for which acid milks are used so successfully at the present time.) There were many ups and downs, but after four months' illness she finally recovered. During the next two years her health was fairly good, but she was not robust. Teething and walking were late.

From early childhood up to adult life, and, indeed, until a few months ago, indigestion was a frequent source of trouble, the special offenders being fatty and starchy foods. *X*-ray examination of the intestinal tract was done two years ago, and showed no abnormality.

During the last six months she has taken 4 to 5 ounces of *B. acidophilus* milk twice daily, and this has agreed with her well. She feels much better generally, and does not get indigestion now after eating fatty articles of diet, although there is still some difficulty with the starches.

The interesting point is, that on a diet containing a lactic acid milk, which in my experience is easily the best diet for dyspepsia and marasmus in infancy, this patient has greatly improved in her general health; indeed, she looks the picture of health, and rarely suffers from symptoms of indigestion.—I am, etc.,

BERNARD MYERS, M.D.

London, W., July 13th.

MICROCEPHALY

SIR,—I am in complete agreement with Dr. Noel Burke on this subject. Etymologically, of course, "microcephalic" means small-headed, and it is quite true that in many aments the skull is smaller than normal. Indeed, so generally is this the case, that if the term is applied in this wide sense it really ceases to have any practical or particular use. On the other hand, if it is restricted to a special type of small-headed aments, it is of very great use. It has long been so restricted, not only in England, but also in Europe and America. This connotation is well understood, and the type to which the term refers is, as Dr. Burke rightly remarks, quite as distinctive as mongolism. I therefore consider that any attempt to alter its generally accepted meaning, as suggested by Dr. Berry, can only lead to confusion, and is to be deprecated.—I am, etc.,

A. F. TREDGOLD.

London, W., July 7th.

ELECTROCARDIOGRAPHIC CHANGES IN ANGINA PECTORIS

SIR,—In his exhaustive and very instructive article entitled "Observations on angina pectoris," in the *Journal* of May 23rd, Dr. John Cowan has unfortunately omitted to mention the "specific" electrocardiographic changes that have been observed *during* an attack of angina pectoris, and their importance in elucidating the probable causation of this important trouble. It is true that Dr. Cowan does state, "the electrocardiograms were frequently abnormal," and he also mentions certain changes that he observed. But he does not state whether these changes were observed during the attack only. It appears, however, that those electrocardiographic changes were rather the resultants of some permanent myocardial defects. Recently, however, various observers[1 2] have shown that in the greater number of cases so examined certain electrocardiographic changes can be observed during an attack of angina; that these changes are, moreover, temporary only and reversible—that is, that soon after the attack the electrocardiogram returns again to its previous appearance; and, what is most important, that the changes in the electrocardiogram are of a "specific" kind, and that they are similar to those met with in permanent coronary occlusion—namely, a deviation in

[1] Feil, Harold, and Siegel, M.: *Amer. Journ. Med. Sci.*, 1928, clxxv, 255.
[2] Parkinson, J., and Bedford, D. E.: *Lancet*, January 3rd, 1931.

the ST portion of the electrocardiogram and alterations in the T-wave.

The importance of these observations has been enhanced materially by the recent work of Wood and Wolferth,[1] who have succeeded experimentally in producing in animals, temporarily, interference with the blood supply of part of the heart, and the electrocardiogram tracings during and after such interference were similar to those obtained by them from patients during and after an attack of angina respectively.

As regards the immediate cause of the pain, both in permanent coronary occlusion and its similar temporary occurrence in angina pectoris, I would suggest that the pain is produced by the nerve irritation on account of the proximate contiguity of injured and uninjured tissues, analogous to the severe pain produced by spreading gangrene caused by thrombosis of a vessel, and that it is not due to the actual ischaemia. This will explain the absence of cardiac pain in such conditions as mitral stenosis, congestive failure, and anaemia. It will also explain the fact that anginal attacks disappear with heart failure, because there is then no longer a sharp line of demarcation between injured and healthy tissue, the "healthy" tissue being in the circumstances to some extent "injured" tissue.—I am, etc.,

Capetown, June 18th. S. E. KARK, M.D.

REFRESHER COURSES FOR SHIP SURGEONS

SIR,—Dr. Haslett Frazer's comments in a letter in the *Journal* of June 27th (p. 1139), which is wrongly entitled "Refresher courses for ship surgeons," are evidence of a rather careless perusal of the post-graduate course for ship surgeons, which the British Medical Association has been at such pains to promote. The refresher course is Part III only of this scheme. Part I covers ship hygiene, Shipping Acts, and quarantine procedure. Part II covers tropical medicine and hygiene.

Dr. Frazer is of the opinion that the course does not touch the real requirements of ship surgeons, and goes on to instance the need for (1) the *absolute* diagnosis (the italics are my own) of the exanthemata and the various forms of conjunctivitis, (2) a knowledge of venereal diseases, (3) the full preparedness to deal with any surgical emergency. Part I disposes of his first objection. Section D, a most important one, goes into the question of the International Sanitary Convention and the quarantinable fevers; in this the subjects of clinical recognition and visits to fever hospitals are the prominent features. As for other fevers, they are provided for in Section C, with special regard to the isolation facilities and difficulties at sea. Conjunctivitis does not come within Part I, and it is not a matter for quarantine jurisdiction; but in one of its more serious and infectious forms—trachoma—it is a vital matter to immigration authorities, and, therefore, to the shipping companies; it is included in Part III, under eye diseases.

The question of the major surgical emergencies is, however, a debatable subject. It should be said that it was not the committee's intention that this, the refresher course, should compete with the usual post-graduate courses. Whatever shortcomings the post-graduate surgical course may have with regard to actual surgical practice, it would be ridiculous to imagine that this course, Part III, of four weeks' duration only, could cover not only the pertinent medical and surgical subjects, but also offer practical surgical facilities, which not even the established schools with their limited material are able to do. Such an ambition would, indeed, lead the candidates very widely astray. The course was intended not only to supplement post-graduate work, but to supplement it and select the subjects, or aspects of subjects, in a way which would constantly keep in the foreground the requirements, the facilities, and the difficulties at sea. So with surgery the particular point was rather to heighten the prognostic sense as to what was of real urgency, with the implication that, wherever reasonably possible, a surgical operation case, with respect to all the personal and material problems, is better left until the patient is put ashore. The choice of other medical and surgical subjects in Part III needs no special pleading. Where the period of incapacity can be shortened, as with skill in the diagnosis and treatment of fractures, or with the modern treatment of burns or scalds, varicose veins, and ulcerated veins, the twofold duty to the sufferer and to the shipping company becomes obvious.

The course is, however, restricted; it cannot, for instance, range over the whole field of anaesthetics—it selects for consideration only those three or four for study which are indicated under the varying temperatures and the difficulties of administration at sea. The course touches on certain subjects in which there has been acknowledged advance, such as diabetes and pernicious anaemia, or a subject like dietetics, of very great importance on board ship in the avoidance of deficiency diseases. Likewise for every item the underlying motive has been, first, to aid the ship surgeon in his special sphere and to increase his value to his company, and to keep him in touch with modern knowledge so far as it can be applicable to his work.

Part II, tropical diseases and hygiene, is of vastly increasing concern to the shipping companies who trade in the Tropics or who advertise tropical cruises. The failure to recognize certain common tropical disorders has reflected adversely on the surgeon, and has caused considerable trouble both to company and to passengers. The surgeons themselves admit the need for such instruction.

It is a little disappointing, however, to find the value of Part I unappreciated by anyone who has had experience as a ship surgeon. Few general practitioners retain a memory of anything but the general principles of hygiene, and ship hygiene bristles with difficulties. Owing to the surgeon's ignorance the hygiene is left entirely to the executive whose knowledge of it is acquired by routine only. The ship surgeon is rarely consulted except as a matter of courtesy, and yet he is the only member of the crew who is qualified by his training to pass an expert opinion. He is at a disadvantage, however; he knows only by routine the nature of intakes and exhausts, the disposal of tanks, the storage of water, the means of contamination, and the best method of sterilization. He does not understand why the crew, passenger, and cargo spaces are disposed in the way they are. That is why ship construction is included in the course. So it is with every subject in this part; the reasons are adequate in every case for their inclusion.

The only objection perhaps to the whole scheme is the shortness of time allotted to each part; in view, however, of the present depression the companies have been very generous in meeting these proposals.—I am, etc.,

Liverpool, July 10th. T. GWYNNE MAITLAND.

SYSTEMIC INFECTION AFTER TOOTH EXTRACTION

SIR,—Dr. Leonard Abrahamson's report (*Journal*, July 4th, p. 8) of three fatal cases of subacute bacterial endocarditis following tooth extraction (two cases) and tonsillectomy (one case) is a valuable contribution to the growing volume of evidence of the danger of opening up fresh channels of infection in patients whose resistance

[1] Wood, J. C., and Wolferth, C. C.: *Arch. Intern. Med.*, 1931, xlvii, No. 3.

is already seriously impaired, and especially those who have other lesions, such as a quiescent endocarditis. One of his cases, indeed, suggests that the infection of the tooth sockets, which induced the medical and dental advisers to undertake the extractions, was not a primary cause, but a late secondary effect, of infection, and this is not at all an infrequent type of case. A course of vaccine therapy before operative intervention, which Dr. Abrahamson recommends, is theoretically sound, but the isolation of specific organisms from the gum pockets is generally problematical; the preparation of an autogenous vaccine occupies valuable time, during which serious complications may occur, and the results are too unreliable. A simpler, quicker, less expensive, and, I believe, more effective therapy lies in the giving of two or three erythema doses of ultra-violet light to destroy the toxins already floating in the blood and to fortify the patient's resistance. The results (although in the nature of the case proof is impracticable) certainly encourage the belief that this is a prophylactic measure of very great value against what is undoubtedly a formidable risk. It has also a very wide range of usefulness.—I am, etc.,

London, N.6, July 7th. F. TALBOT.

MUCIN AS A THERAPEUTIC AGENT

SIR,—I was pleased to observe in your much appreciated and instructive "Epitome of Current Medical Literature" for June 27th an abstract of the work of S. J. Fogelson (*Journ. Amer. Med. Assoc.*), under the title of "Treatment of peptic ulcer with mucin," and to see that American physicians have now endorsed my belief in its superiority to all other treatment in many throat and stomach complaints. Dr. Fogelson, so far as I can gather, pronounces this as an original research; but thirty years ago, in a pamphlet entitled "Mucin in desiccation, irritation, and ulceration of mucous membranes," I emphasized the efficacy of mucin as opposed to bismuth for the soothing and healing of gastric ulcer. While working at the Central London Throat, Nose, and Ear Hospital it had been borne in on me that deficiency of mucin was the cause of much of the trouble met with, and that this shortage should be met by the application of properly prepared mucin. I observed also that indigestion and gastric pain frequently accompanied dryness of the fauces and pharynx. In 1905 I enunciated in *Mucin and Malignancy* the principle of the mucin treatment of throat and stomach, and after all these years of practice I can only repeat and emphasize the importance of this treatment. Messrs. Burroughs, Wellcome and Co. were the pioneers in the preparation of the pleasant "elixoid mucin" and the tabloids containing mucin and soda; these have held the field hitherto. It seems possible that powdered hog's stomach acts only by virtue of the mucin it contains.—I am, etc.,

London, W., July 7th. W. STUART-LOW.

TREATMENT OF DYSMENORRHOEA

SIR,—I am in complete accord with the letter of Dr. E. Sloan Chesser as to the efficacy of static wave currents in dysmenorrhoea. I usually employ it in conjunction with diathermy, but I did not refer to it in my previous letter as the number of efficient static machines in the hands of medical men in this country is so limited that the employment of these applications is but rarely possible. In America, where the value of static treatment is so much more recognized, wave applications are the recognized remedy for simple dysmenorrhoea.—I am, etc.,

Cheltenham, July 11th. J. CURTIS WEBB.

Obituary

SIR CHARLES BEDFORD, M.D., D.Sc., LL.D., D.C.L.

Lieut.-Colonel I.M.S. (ret.)

Lieut.-Colonel Sir Charles Henry Bedford, Bengal Medical Service (ret.), died at Woking on July 8th, aged 65. He was born on June 19th, 1866, in Edinburgh, the youngest son of the late F. W. Bedford, LL.D., head master and governor of Heriot's Hospital, Edinburgh, and was educated at the University in that city, where he graduated as M.B. and C.M. in 1887, as B.Sc. in 1889, as M.D., with honours, and as D.Sc. in 1892; also taking the M.R.C.S. diploma in 1888.

Entering the I.M.S. as surgeon on September 30th, 1889, he became lieutenant-colonel after twenty years' service, and retired on December 18th, 1911. After a few years' military duty he was appointed professor of chemistry in the Lahore Medical College, and chemical examiner to the Punjab Government; and a few years later was promoted to the corresponding post in Calcutta. In 1906 he organized the Central Excise Laboratory for India, of which he was appointed director, and held that post till he retired from the Service in 1911. He rejoined for service in the war of 1914–18, and in 1915–16 was Deputy Chief Commissioner for Medical Services under the Ministry of National Service, London, and in 1917–19 Commissioner for the London, South-Eastern, and East Anglian districts. In 1926 he originated the King Alfonso Chair of Spanish Studies at Oxford, and in 1930 the Anglo-Spanish and Spanish-American Institute of London. He had a world-wide reputation for his researches on alcohol, both potable and industrial. He was knighted for his scientific services on December 11th, 1911, and in 1913 he received the honorary degree of LL.D. from St. Andrews, in 1923 the same degree from Edinburgh, and in 1924 that of D.C.L.Oxon; and in 1929 was made Knight Grand Cross of the Spanish Order of Civil Merit.

Sir Charles Bedford was the author of *The Enteric Fever of India*, 1893; *History of George Heriot's Hospital*, 1901; *Memoirs of F. W. Bedford, D.C.L., LL.D.*, 1902; *Handbook of Urine Analysis*, 1902; *Elementary Hygiene*, 1903; *Symptoms and Treatment of Poisoning*, 1903; and of many scientific reports on his special subject—alcohol and its uses. He also edited the *Indian Medical Gazette* in 1898. In 1901 he married Jane Beatrice, daughter of W. A. Carter, M.I.C.E.

THE LATE MR. E. B. TURNER

Dr. ERIC PRITCHARD writes:

I feel that some posthumous acknowledgement is due to the late E. B. Turner for his many good offices in reconciling a large section of the medical profession to the new ideas embodied in the welfare movement, at a time when its activities were very unpopular with the majority of practitioners, as well as with the British Medical Association. Owing to the respect, and I think I may say affection, in which Turner was held by his colleagues in the profession and in the counsels of the B.M.A., he had many opportunities for exercising his influence at headquarters as well as among his fellow practitioners. He became a convert to the ideas of the welfare movement after he had listened to the evidence brought before the Medico-Sociological Committee of the British Medical Association which was appointed in 1920 to consider the whole question of the relationship of the medical profession to this movement; and of this committee he was an active member. He told me himself that before he heard this evidence he took the same views

as the majority of the profession—namely, that the movement was likely to interfere with the just prerogatives of practitioners by undermining their influence in the home, and by depriving them of the valuable experience connected with practice among children. Shortly after the publication of the report of this committee in 1921—a report which only grudgingly admitted the merits of this new movement—Turner joined the executive committee of the National Baby Week Council, and from that time forward entered whole-heartedly into the spirit which activated the great voluntary movement which has its headquarters at Carnegie House. In spite of his advanced age and the many calls upon his time and energies, Turner attended frequent committees connected with the various phases of the welfare movement, and served as its representative on many other national organizations. His loss will be acutely felt by the members of the National Baby Week Council, of which at the time of his death he was vice-chairman of the executive committee as well as a vice-president; as also by the members of the many other national associations quartered in Carnegie House.

We regret to learn of the death of Professor CARROLL GIDEON BULL, M.D., of the bacteriological department of Johns Hopkins School of Hygiene, at the early age of 46. It was he who as a young worker at the Rockefeller Institute brought over the first real gas gangrene (*B. welchii*) serum to be tried in France during the war. Carroll Bull was a member of the American Association of Pathologists and Bacteriologists, and of the Society of American Bacteriologists, and at the time of his death was professor of immunology in the Johns Hopkins School of Hygiene and Public Health.

Universities and Colleges

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University:—*St. Bartholomew's Hospital Medical College*: Mr. J. Basil Hume and Mr. J. Paterson Ross (Surgery); *Westminster Hospital Medical School*: Dr. W. Ernest Lloyd (Medicine); *St. George's Hospital Medical School*: Mr. B. Hartop Burns (Surgery), Mr. W. S. Duke-Elder (Ophthalmology), Dr. D. Hope Freshwater (Dermatology), Mr. P. J. Jory (Oto-rhino-laryngology), Mr. Harold Taylor (Obstetrics and Gynaecology); *London Hospital Medical College*: Dr. R. Alan Brews; *London (Royal Free Hospital) School of Medicine for Women*: Dr. Daniel T. Davies (Medicine).

The annual report of the superintendent of the Brown Animal Sanatory Institution records that five lectures on diseases of bacteria were given at the Royal College of Surgeons in December last by the superintendent, in accordance with the will of the late Mr. Brown. The superintendent has continued his work on ultra-microscopic viruses, and some additional work on transmissible bacteriolytic agents has also been carried out. Dr. Nathan Raw has continued his researches on human, bovine, and avian bacilli, with special reference to their value in the immunization of animals and man against tuberculosis. The appointment of Mr. F. W. Twort, F.R.S., as superintendent of the institution has been continued for one year from June 1st, 1931.

The annual report of the Graham Legacy Committee states that the Graham Scholarship is held by Mr. C. L. Oakley. The activities of the laboratories continue along the usual lines. Grants amounting to £160 were made by the committee to six workers. The fund was founded to aid research in the School of Advanced Medical Studies connected with University College Hospital, and has for its object the prevention, cure, and alleviation of human disease and suffering. Professor A. E. Boycott, F.R.S., has been reappointed director of research under the scheme for one year from September 1st, 1931.

The regulations for the Mary Scharlieb Research Studentship have been approved. It has been founded under the will of Miss Mary Ethel Sim Scharlieb in memory of her mother, Dame Mary Ann Dacomb Scharlieb, and will be of the annual value of £250, for award from time to time, provided there is a candidate of sufficient merit. The award will be made for one year in the first instance, but will normally be renewable for a second year if the student's research is progressing satisfactorily. Candidates must be graduates of the University, and must be either medical practitioners or in possession of qualifications which, in the opinion of the Senate, would enable them to undertake post-graduate research of the kind indicated.

Regulation 3 for the Diploma in Psychological Medicine has been amended to read as follows:

The examination for the Diploma is open to any candidate whose name is on the *Medical Register*, provided that, before being admitted to Part B, the candidate shall either (*a*) have held for not less than six months a resident, or whole-time, appointment at an institution (or institutions) for (i) mental diseases (psychiatry) or (ii) mental deficiency, recognized for the purpose, or (*b*) have attended for not less than twelve months the practice of such institution (or institutions), or such other practice as may from time to time be approved by the University, provided that a candidate who under Regulation 4 professes a higher knowledge of mental diseases (psychiatry) shall have held a resident appointment or carried on approved practice at an institution in category (i) and one who professes a higher knowledge of mental deficiency at an institution in category (ii).

ST. BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE

The following scholarships and prizes have been awarded:

Kirkes Scholarship: J. H. B. Beal. *Senior Scholarship*: K. A. Latter. *Junior Scholarship*: D. F. E. Nash. *Harvey Prize*: E. W. Bintcliffe. *Foster Prize*: K. A. Latter. *Treasurer's Prize*: G. L. Bohn. *Bentley Prize*: E. R. Langenberg. *Wix Prize*: J. M. Jackson. *Matthews Duncan Prize*: J. M. Jackson and M. Westwood (equal). *Brackenbury Scholarship in Medicine*: C. H. S. Harris. *Burrows and Skynner Prizes*: C. H. S. Harris. *Brackenbury Scholarship in Surgery and Willett Medal*: J. E. A. O'Connell. *Walshaw Prize*: J. H. B. Beal. *Shuter Scholarship*: J. Smart.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The name of P. G. G. Unnithan should be added to the list of successful candidates at the recent school examination, published last week (p. 78).

The following candidates have been approved at the examination indicated:

ACADEMIC D.P.H.—Katherine Barnett, H. L. W. Beach, T. C. Lonie, G. R. Marcano, S. M. Rafi, A. M. Samarasinghe, C. R. Selous Jones, S. P. Srivastava, Sarah M. F. Walmsley.

UNIVERSITY OF SHEFFIELD

The following candidates have been approved at the examinations indicated:

M.D.—E. S. Clayton, J. N. Gale.

FINAL M.B., CH.B.—J. E. Edson (with second-class honours and distinction in obstetrics and gynaecology), A. W. R. Eardley, T. A. Hunt, S. K. Pannikar, D. R. Rigg.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

At the later Summer Commencements, held on July 3rd, the following degrees were conferred:

D.Sc. (*hon. causa*).—Cornelius U. A. Kappers, M.D.

M.D. (*hon. causa*).—Sir John Rose Bradford, Bt., K.C.M.G., M.D., Sir Foster Reuss Newland, K.C.M.G., M.B.

M.D.—T. C. Foster, B. Moshal, A. Sachs.

M.CH.—H. A. Brittain, T. J. Millin.

M.A.O.—W. S. Dickson.

M.B., B.CH., B.A.O.—T. M. R. Ahern, Ruth R. Armstrong, J. C. M. Branbell, Marjorie L. Campbell, Margaret D. Gregg, W. A. Hill, F. C. Jackson, D. G. Kennedy, M. G. Leane, N. H. Leask, A. H. Lisney, B. O'Brien, T. F. O'Donnell, Elizabeth K. Roberts, C. Ryan, H. V. Tighe.

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following candidates have been approved at the examinations indicated:

M.D.—T. C. Foster, B. Moshal, A. Sachs.

M.CH.—T. J. Millin, H. A. Brittain.

M.A.O.—W. S. Dickson.

FINAL M.B.—*Part I, Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology*: *I. S. M. Pringle, *Marjorie R. E. Boyd, *W. H. E. M'Kee, *Emily M. Beath, D. M. Ahern, Agnes Montero, Eileen M. Kennedy, A. B. Warren-Darley, N. Jackson, P. B. Hafner, J. J. Martin, H. Mahfud, H. S. Barber, H. R. Davies, C. C. Langford, C. W. N. Semley, J. A. Maher, C. J. Mullen, E. G. Ashton, H. T. Ryan, S. M. Freeman, G. C. V. O'Driscoll, N. Anderson, J. A. M'Elveen, I. T. F. Wiley, E. Howitt. *Part II, Medicine*: *B. O'Leary, G. A. Wray, I. M. R. Ahern, D. B. Bradshaw, H. V. Tighe, J. B. Fleming, H. F. G. Irwin, F. C. Jackson, M. G. Leane, I. G. M'Intyre, D. G. Kennedy, A. D. Barber, D. H. S. Boyd, W. A. Hill, T. J. O'Sullivan, J. C. M. Branbell, J. L. Martin, N. H. Leask, R. C. Sutton, H. S. Mason, E. FitzG. Burton, J. Elliman. *Surgery*: *Margaret D. Gregg, Elizabeth K. Roberts, B. O'Brien, T. F. O'Donnell, Marjorie L. Campbell, T. M. R. Ahern, H. V. Tighe, C. Ryan, J. C. M. Branbell, F. C. Jackson, Ruth R. Armstrong, A. A.

Lisney, W A Hill, M G Leane, N H Leask *Midwifery* A A Cunningham, J A Wallace, R D Scott, L L Nel, E W West, G F Harris H J Garland, I King

D P H—*Part I, Chemistry, Bacteriology and Parasitology, Physics Meteorology, and Climatology* H Nelson, G C Dockeray, L L Griffiths, W D Speedy, Nora A Stack, R St J Lyburn, Jane A M Nagle, C P Wallace *Part II, Sanitation (including Sanitary Construction), Public Health Administration, Hygiene and Epidemiology; Sanitary Law and Vital Statistics* G C Dockeray, W D Speedy, H Nelson, Nora A Stack

DIPLOMA IN PSYCHOLOGICAL MEDICINE—*Part II* G W M Scroope

The following prizes have been awarded

Cunningham Memorial Medal and Prize H D O'Brien *John Mallet Purser Medal, and Stewart Medical Scholarship in Anatomy and Physiology* L C Kolb *Medical Travelling Prize and Banks Medal* A H Thompson *De Renzi Centenary Prize* G C Dockeray and H Nelson *Fitz-Patrick Scholarship* B O Brien *Medical Scholarship (Anatomy and Physiology)* A Dolphin *Stewart Medical Scholarship in Physics, Chemistry, Botany, and Zoology* W A Gillespie

* Passed on high marks

UNIVERSITY OF ABERDEEN

At the graduation ceremony on July 7th the following degrees were conferred

M D—B S Cran (awarded honours for thesis), P Henderson, W J Webster

M B, C H B, with second-class honours—W G Davidson, T N Morgan (with distinction)

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly Council meeting was held on July 9th, when the President, Lord Moynihan, was in the chair

Election to Council

The President having announced the result of the poll for the election of three members into the Council (*British Medical Journal*, July 11th, p 79), Mr Graham Simpson, Mr G Ernest Gask, and Mr A J Walton were introduced and took their seats

Mr R M Vick was introduced, and admitted a member of the Court of Examiners

Election of Officers

The following officers were elected for the ensuing year *President*, Lord Moynihan, *Vice-Presidents*, Mr R P Rowlands and Mr Sampson Handley, *Physiological Curator*, Mr R H Burne, *Pathological Curator*, Mr C F Beadles, *Honorary Curator of the Odontological Collection*, Sir Frank Colyer, *Honorary Curator of the Historical Collection*, Mr C J S Thompson

Lectures

The Council elected the following professors and lecturers for the ensuing year

Hunterian Professors—Sir Arthur Keith (six lectures on recent advances in embryology applied to surgical problems), John Percival Hosford (one lecture on some factors in the causation of hydronephrosis), Reginald Theobald Payne (one lecture on excretion urography—intravenous pyelography), Albert Remington Hobbs (one lecture on the puerperal uterus as a surgical problem), John Alfred Ryle (one lecture on the natural history of duodenal ulcer), Henry Albert Harris (two lectures on the comparative anatomical aspect of prenatal, infantile, and adult disease in man and animals, with special reference to bone growth)

Arris and Gale Lectures—Wilfrid Edward Le Gros Clark (two lectures on the structure and connexions of the optic thalamus), Alexander James Edward Cave (one lecture on the morphological and functional anatomy of the human cervical spine)

Erasmus Wilson Lectures—Clement Edward Shattock (two demonstrations on pathology), Cecil Pembrey Grey Wakeley (two demonstrations on pathology), Robert Davies Colley (one demonstration on pathology), Eric Drew Moir (one demonstration on pathology)

Arnott Demonstrator—Sir Arthur Keith (six demonstrations on the contents of the Museum)

Diplomas and Licences

Diplomas of Fellowship were granted to A A Davis and A L Light, and the diploma of Membership to H Singh, these candidates having complied with the regulations of the College

Diplomas were granted, jointly with the Royal College of Physicians in Public Health to 27 candidates, in Psychological Medicine to 13 candidates, in Laryngology and Otology to 5 candidates Licences in Dental Surgery were granted to 40 candidates

Prizes

The Hallett Prize for the examination in anatomy and physiology for the Fellowship concluded on June 12th, was awarded to S G Clayton (King's College) The second Macleghlin scholarship was awarded to R Y Stevenson.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons was chiefly occupied with agricultural business this week, but the Education Estimates were also down for discussion The Long Recess is to begin on July 31st The Pharmacy and Poisons Bill is not in the list of measures which the Government desires to pass through the Commons before that date, and its chance of becoming law before the session ends is small

The Parliamentary Medical Committee has not taken any decision on the Sterilization Bill, which will be introduced by Major Church on July 21st

The Housing (Rural Workers) Amendment Act, the Mining Industry (Welfare Fund) Act, the Sentence of Death (Expectant Mothers) Act, and the Coal Mines Act received the Royal Assent on July 8th

Hygiene on Ships

Mr W GRAHAM, replying to questions by Sir B Peto and Mr Hastings on July 7th, said that the reports of the Shipping Federation Committee on crew accommodation had been considered by the Joint Committee of the Board of Trade and by the Ministry of Health, and certain instructions to the Board's surveyors had been agreed on by the Merchant Shipping Advisory Committee, and would shortly be issued The Shipping Federation had appointed in May, 1929, a special committee to advise owners on the best arrangements which could be made for the comfort and convenience of crews This committee had made two reports relating to the accommodation of seamen other than lascars, which contained a number of valuable recommendations, many of which went beyond the existing Board of Trade regulations A special arrangement of the sleeping berths was suggested which avoided double tiers of bunks, and useful suggestions were made in connexion with washing and sanitary accommodation The importance of adequate ventilation and heating was pointed out The provision of an isolation hospital on all large foreign-going cargo vessels was also recommended The committee, recognizing that the provision of good accommodation would be of little avail unless it was kept clean and in good order, laid stress on the proper supervision and cleansing of the crews' quarters, and suggested the imposition of penalties for failure to keep the accommodation clean These recommendations, as originally made, applied particularly to new ships of 1,500 tons gross and over but the Shipping Federation had agreed with the Board of Trade that they should be adopted wherever practicable irrespective of the size of the ship The reports had been examined in the Department, and also by the Joint Advisory Committee of the Board of Trade and the Ministry of Health on the health of the mercantile marine, and the opinion, both of the Board of Trade and of the Joint Committee was that if the recommendations were followed a material improvement in the standard of accommodation would result The recommendations had also been considered by the Merchant Shipping Advisory Committee, which had expressed the opinion that the recommendations should be of great value The Board of Trade had therefore decided to give its general approval to the recommendations, and to take such action as lay within its power to give effect to them It was circulating to its surveyors particulars of the recommendations of the Shipping Federation Committee, and at the same time was instructing them to ascertain, in the case of all new ships, the proposals as regarded crew spaces as early as possible, so that, if necessary it could approach the owners and builders and discuss with them the possibility of making improvements in design or in fittings where these appeared to be called for in the light of the recommendations To secure improvements on existing ships which fell below present-day standards in such matters as the provision of lavatory and washing accommodation, the substitution of metal bunks for wooden berths, and the proper lighting, ventilation, painting, and cleaning of the crews' quarters, the Board of Trade surveyors were instructed to use their best endeavours.

Ministry of Pensions

Mr. F. O. ROBERTS informed Major Evans, on July 13th, that a review of the experience of the Ministry of Pensions in the handling of the principal war disabilities had been prepared by the Ministry for inclusion in the forthcoming "Official Medical History of the War," which would be issued at an early date. He was entirely in sympathy with the suggestion that the Ministry should produce and issue for general information a comprehensive and scientific record of the experience and achievements of the Ministry in medical and surgical spheres, including treatment of wounds, disorders of the nervous systems, and other diseases. He had under consideration such steps as could usefully be taken in that direction.

Answering Mr. Marcus, on July 13th, Mr. F. O. ROBERTS said that a final award is not, under the statutory regulations, made by the Ministry of Pensions until the man's condition was reasonably stable, each case being considered on its merits and in the light of expert opinion as to the particular ailment or disease. In any event, the man had a right of appeal for a year to an independent appeal tribunal. If a condition due to war service subsequently called for treatment, it could be provided, and allowances could also be paid where justified, notwithstanding that a final award had been made. If, as a result of such treatment, a final award should be found to have been seriously erroneous, a further grant of pension could be made under special sanction.

Housing

The Housing (Rural Authorities) Bill was read a second time by the House of Commons on July 10th. Mr. GREENWOOD explained that the scheme was to help necessitous rural authorities to carry out their responsibilities under the Housing Acts.

Dr. FREMANTLE urged the Ministry of Health to make use of the annual reports of the medical officers of health. The Ministry could call for a definite survey of a particular area regarding housing, leaving aside for the time being the normal report on public health. He advised a survey by the medical officers of health both in the districts and in the counties. Such publicity would go a long way towards showing to all concerned the actual facts and needs.

The Bill extends to Scotland, and Mr. WESTWOOD read an unfavourable report from Scottish Office inspectors upon the housing in Fifeshire villages. Mr. TOM JOHNSTON said that in some country districts no houses had been built under any Act.

The Bill was considered by the House of Commons in committee on July 14th.

Maternal Mortality

Answering Dr. Marion Phillips, on July 9th, Mr. GREENWOOD stated that 139 local authorities had now replied to his circular of December, 1930, concerning maternal mortality. Of these, 102 proposed to make improvements in their maternity services, 13 stated that the circular was still under consideration, and 37 did not at present propose to extend their services. He was sending a further communication to those authorities which had not yet replied to the circular.

Napsbury Mental Hospital.—In reply to Mr. Messer, on July 2nd, Mr. GREENWOOD said he knew that one hundred mental patients were compelled to sleep on the floor at Napsbury Mental Hospital owing to lack of accommodation, and that the Middlesex County Council submitted plans as far back as 1924 which had only recently been passed by the Board of Control. Approval had recently been given to the first section of the scheme, which comprised all the administrative buildings and accommodation for 1,046 patients.

Nursery Schools.—On July 6th Mr. MORGAN-JONES, replying to Mr. Hastings, said that there were 44 nursery schools recognized by the Board of Education, 23 being provided schools and 21 voluntary schools. There were 11 provided and 3 voluntary schools in course of erection. In addition, preliminary proposals had been sanctioned for 12 provided schools. Practically all the schools now being built were open-air schools.

School Accommodation for Defective Children.—On July 7th Mr. WESTWOOD, replying to Miss Lee, said that the total number of places for backward and defective children available in special schools and classes in Scotland was 12,852. This figure included accommodation for blind, deaf-mute, and other physically defective children as well as for those mentally defective. More accommodation was still required for mentally defective children. This matter was engaging the attention of the Scottish Education Department, and the Secretary for Scotland hoped that measures would soon be taken to effect an improvement.

Water Supply in Schools.—In reply to Mr. Ede, on July 9th, Mr. LEES-SMITH stated that he had inquired into the question of the water supply in the Nottinghamshire schools. The local education authority was alive to the position. In all except three schools water for washing was now provided, and except in about seven cases drinking water was available, if not on the school premises, at no great distance. Answering Mrs. Manning, on the same day, Mr. LEES-SMITH said there was only one school in Herefordshire where a water supply was not available. He understood also that at four Herefordshire schools new water supplies were contemplated. It was the Board of Education's practice to take up all cases where the water supply appeared to be unsatisfactory and capable of remedy.

Deaths in Prisons.—Replying to Mr. Freeman, on July 9th, Mr. CLYNES said that during the twelve months ended May 31st, 1931, there were eight natural deaths in convict prisons in England and Wales, twenty-two in local prisons, and one in a Borstal institution. Of suicides there were none in convict prisons, three in local prisons, and two in Borstal institutions. In compiling any return of attempted suicides there was a difficulty in determining whether certain cases were real attempts at self-destruction or feigned attempts undertaken for some other purpose. So far as could be ascertained there was one case of attempted suicide in convict prisons, twenty in local prisons, and one in Borstal institutions.

Red Cross Rheumatism Clinic.—Replying to Mr. White, on July 9th, Mr. GREENWOOD said the British Red Cross Society had recently published a report on the work of the clinic for the treatment of rheumatism at Peto Place. He was satisfied that the clinic was fulfilling a useful purpose, but it would be premature to attempt to assess the results of its work. Suggestions for the extension of this work in other localities were under consideration, and if any proposals were submitted to his department they would receive careful examination.

Encephalitis and Vaccination.—Replying to Mr. Freeman, on July 9th, Mr. GREENWOOD said there was no reason to associate the deaths of twin children at Wigston, near Leicester, from post-vaccinal encephalitis, with the use of Government lymph. He did not propose to take any steps to prevent the further use of Government lymph in this district. Mr. FREEMAN asked if compensation was payable, and whether the Government had sent an expression of sympathy to the parents. These questions were not answered. Answering further questions by Mr. Freeman on the same date, Mr. GREENWOOD said he saw no necessity for any further inquiry at the present time into the question of vaccination, as the subject had been fully investigated by the Committee on Vaccination, whose reports were issued in 1928 and 1930. Mr. FREEMAN asked if Mr. Greenwood could announce any decision about the possible inquiry which he mentioned to the House a year ago into the whole administration of the Vaccination Acts. Mr. GREENWOOD said he could not.

Physique of Recruits.—On July 13th Mr. SHAW, replying to Mr. Louis Smith, said that in the recruiting year ended September 30th, 1921, 51,021 persons were rejected for the Army for physical or mental reasons. This was a percentage of 48.1 of the men served with notice papers. In 1922, 59,736 men were rejected, percentage 55.9; in 1923 49 559 were rejected, percentage 57.6. The figures for 1924 were rejections 49,245, percentage 58.3; 1925 52 207 and 58 5; 1926, 48,800 and 58.8; 1927, 50,396 and 60 1; 1928 47 552 and 57.3; 1929, 39,359 and 54.4; and 1930, 35,425 and 53.1.

Notes in Brief

On July 13th Mr. Benn informed Miss Rathbone that there was no general compulsory notification of births or marriages in any province in India.

On June 6th, 1931, 892,450 persons were in receipt of poor relief in England and Wales (excluding rate-aided patients in mental hospitals, casuals, and persons in receipt of domiciliary medical relief only).

THE BOARD OF CONTROL

REPORT FOR 1930

Part I of the seventeenth annual report of the Board of Control, for the year 1930, is published to-day.[1] The introductory paragraphs refer to the passing of the Mental Treatment Act in July, 1930, and the steps taken to bring it into operation, as the most important events in this sphere of work during the twelve months under review. "We believe that this Act marks an epoch in the treatment of mental disorders in this country, though some years may elapse before its full possibilities can be realized." A convenient summary points out the directions in which the Act provides opportunities for progressive development in the care of persons suffering from mental disorder. The Board is convinced that if the benefits of the Act are to be brought fully within the reach of those for whom they are intended, full co-operation is necessary on the part of the public, the medical profession, and local authorities alike.

PROGRESS UNDER THE MENTAL TREATMENT ACT
